**INFILTRATION ANESTHESIA IN VAGINAL
PLASTIC OPERATIONS**HARVEY B. MATTHEWS, M.D., F.A.C.S., and
VINCENT P. MAZZOLA, M.D., F.A.C.S., Brooklyn*From the Department of Obstetrics and Gynecology, Long Island College Hospital*

In attempting to prevent the tragic surgical accidents which at times inevitably occur, the matter of the selection of anesthesia is an important factor. This is especially true in gynecology since a great number of operations are elective procedures. In the presence of medical complications such as heart trouble, kidney trouble, hypertension, diabetes, and respiratory infections, inhalation anesthetics are often contraindicated. For imperative surgery in these cases, local anesthesia has been employed and has proven to be much less dangerous. It follows therefore that such anesthesia should be safe for individuals in good physical condition. Furthermore, it is a well-known fact that a general anesthesia is far from being perfectly safe in all cases. The works of Bartlett and Simmons,⁴ Thornton,²⁰ Kaye,¹⁰ Rollison,²² and many others, substantiates this fact. Prolonged anesthesia predisposes to shock, acidosis, dehydration, and liver damage. With these dangers associated with general anesthesia, a number of surgeons advocate the use of spinal anesthesia. While this type of anesthesia has its adherents, notably Cooke,⁸ Bower, Clark, and Burns,⁵ Babcock,³ and Rapoport,²⁰ the dangers from its use are greater than

that for general anesthesia. Postoperative complications have been reported by Brown and Debenham,² Arnheim and Mage.²

A more detailed study of the various anesthetics for surgical procedures reveals the fact that local anesthesia is safer than inhalation narcosis. Of the various types of regional anesthesia employed, infiltration is the simplest and safest. While this form of narcosis has been used by Reclus²¹ in France, and Schleich²⁴ and Braun⁶ in Germany, and in this country by Hertzler¹⁴ and Allen¹ infiltration anesthesia did not make much progress in gynecology in the United States until Gellhorn¹² reported extensive plastic work, including vaginal hysterectomy, under local anesthesia. His work has stimulated considerable interest in this subject. Later, reports by Greenhill,¹³ Falls,¹⁰ and Davis⁹ have added much to point out the advantages of local anesthesia in gynecology and confirm the results of earlier reports (Ruge²³ and Farr¹¹).

Bearing these facts in mind, we have been gradually extending the use of local infiltration anesthesia in our gynecological work. It is, therefore, the purpose of this paper to report the results of 780 gynecologic plastic operations

performed on 443 cases, under infiltration anesthesia from 1925 to 1935 on the gynecological service of the Long Island College Hospital*. These procedures are listed separately but more than one procedure was usually carried out during the operation, for example, dilatation and curettage, amputation of the cervix, anterior colporrhaphy, perineorrhaphy and / or other combined procedures

made by the operator. There should always be a sympathetic anesthetist, armed with proper equipment, standing by to encourage the patient if she is uneasy. The patient should be made as comfortable as possible during the operation.

It is important to note at this time that sensations about the vaginal tract differ as to acuteness. In all of the external parts and the lower third of the vaginal tract sensation is very acute

Fig 1 Infiltration for towel clips

Fig 2 Infiltration for vaginal outlet including labia majora

Fig 3 Infiltration for vulvectomy

Technic

The routine preoperative preparation for vaginal infiltration anesthesia is as follows. The evening preceding operation, the patient is given one tablet of veronal (seven and one-half grains) to secure a good night's sleep. In the morning she is given (two hours before operation) one fourth grain of morphine and 1/200 grain of scopolamine. One-sixth or one-eighth of a grain of morphine and 1/200 grain of scopolamine are administered one half hour before the operation. The second dose of morphine may sometimes be eliminated and the scopolamine given alone. This depends upon the individual patient. It is also well to keep the patient in a dark room and as quiet as possible. During the operative procedure there should be absolute quiet except for an occasional remark of encouragement.

*We wish at this juncture to express our keen appreciation to Drs. Wm. A. Jewett and Geo. W. Phelan for the use of cases from their respective services, as well as to all others on our Staff who contributed cases.

Hence Ruge and Farr suggested anesthetizing the entire vulvar circumference in pelvic procedures (Fig 2). The vault and upper parts of the vagina have very little sensation. The cervix and uterus are not very sensitive to incisions, volsellum forceps, or needle punctures, but are quite sensitive to stretching, as in dilatation of the cervix. Also, the mucosa of the cervix and the endometrium of the uterine cavity have very little sensation, but will not stand a thorough curettage without anesthesia. The same may be said of the peritoneal investment of the uterus, which should not be incised without some infiltration.

For the local infiltration anesthetic we have used one per cent novocain in all operations. Solutions of 0.5 and 0.25 per cent have been used with good results as reported by Gellhorn¹². Since we originally started with one per cent, we have continued to use this strength so that our technic is uniform. However since the weaker solutions produce the same effects, it might be advisable to use them

To each thirty c.c. (1 oz.) of the anesthetic solution to be used is added two drops of 1:1000 epinephrine. The quantity of solution used depends on the nature and extent of the operative procedure. Usually not more than 120 to 150 c.c. (4 to 5 ozs.) of solution is necessary for the most extensive vaginal procedure.

The description of the technic for the various vaginal operations is as follows:

Fig 4 Infiltration for dilatation and curettage

Fig 5 Infiltration for operations on cervix.

Fig 6 Infiltration for urethrocele

Operations on external vaginal outlet We have done twenty-six operations in this group (Table III-A).

A median point on the mucocutaneous junction of the perineum is anesthetized intradermally. This is extended to a point midway between the anus and vaginal outlet. Using this point as a station the vulva is anesthetized laterally. A crescent-like injection is made from above, which meets the lower field. It is started preferably over the external ring of the inguinal canal on each side, making the injection fairly deep and liberal at this point to thoroughly block all fibers of the ilio-inguinal and genitocrural nerves, as they emerge from this opening to be distributed to the tissues of the labia majora (Fig 1, 2, and 3).

Perineum and posterior vaginal wall A point on the perineum midway between the anus and vaginal outlet is anesthetized intradermally. This establishes a station through which the long needle is entered. In the event of an extensive laceration extending up to or including the sphincter ani, this point can be made just within the vaginal outlet (Fig 1, 10, and 11).

The long needle is entered here and passed up in the middle line, injecting as it is advanced as far as the contemplated field of operation. About ten c.c. of solution is needed. If the plane is quite thick it is

best to pass the needle well below the vaginal mucosa in the deeper planes, as the solution can better diffuse in these deeper tissues. However, when dealing with an extensive laceration with rectocele, where the rectum and vaginal mucosa are in close contact, the needle should be passed just beneath the vaginal mucosa. By injecting the solution as the needle is advanced, the solution separates the plane of tissue and there is less danger of the needle puncturing the rectum.

Having made the midline injection, the needle is partially withdrawn and directed slightly laterally and upward first on one side and then on the other, using in each an additional five or ten c.c., depending upon the extent of the field. Similarly, a third or fourth injection can be made just lateral to the preceding until practically the entire vaginal canal except the roof has been infiltrated. A crescentic-like injection, made subcutaneously with a long needle around the vaginal outlet and carried up on each side the full extent of the field, completes the anesthetizing process.

If a perineorrhaphy is to be done, and the tear involves the sphincter, the anal canal must then be anesthetized. This is accomplished by making four injections around the lower bowel and into the sphincter. This should be followed by dilatation of the anus which will assist in diffusing the solution into the various layers. This method of injection gives a perfect anesthesia and facilitates the operation through the separation of the different planes of tissues by the injected solution (Fig 11).

Anterior wall operations Of this group, we have done 304 operations (Table III-B). A point on the cervix is infiltrated and then grasped by a volsellum and pulled down. With the cervix well down and on the stretch, the submucous tissues between the

Fig 7 Infiltration for anterior colporrhaphy

Fig 8 Infiltration of bases of broad ligaments

Fig 9 Infiltration of bases of broad ligaments

cervix and urethral opening are well-infiltrated (Fig 7), carrying the infiltration well out laterally to permit free exposure of the deep fascia in the subsequent dissections (Fig 6 and 7)

Cervix operations Of this group we have done 143 operations (Table III-C). The cervix is anesthetized by drawing it down with the volsellum and making a free sub-mucous infiltration around its neck, and at the junction with the vaginal vault. In making this injection in front care should be exercised not to injure the bladder. A long needle is used. This is directed up in the long axis of the cervix on each side, just within the cervical tissues, to a depth of from two and one-half to five cm (1 to 2 inches) injecting as the needle is advanced.

In a few minutes a fair degree of dilatation can be done without pain, when curettage, trachelorrhaphy, excision or amputation of the cervix can be performed. It is to be noted here that thorough curettage of the body of the uterus is not very satisfactory under local anesthesia but a

limited curettement is very well-tolerated after the above injections (Fig 4 and 5)

Vaginal hysterectomy The perineum and cervix are anesthetized as described above. A long needle is introduced to one side of the cervix to the depth of four to five cm ($1\frac{1}{2}$ to 2 in). The needle is directed in a somewhat lateral direction, in order to strike the nerve trunks before they have undergone their ultimate division. The needle is introduced slowly and carefully so that the blood vessels and perhaps any coils of intestines with which it may come in contact will not be unduly injured. After the needle has been satisfactorily introduced more solution is injected as the needle is withdrawn. Do not be "stingy" with the anesthetizing solution. This process is repeated on the opposite side. Injections are also made on the anterior and posterior walls. In the anterior wall, injections are made similar to those described above for operations on the anterior wall. For the posterior wall, injections are made just through the mucosa. The bladder is first freed from the anterior wall of the uterus

Fig 10 Infiltration for posterior colporrhaphy

Fig 11 Infiltration for complete laceration of perineum

Fig 12 Infiltration for vesicovaginal fistula.

Fig 13 Infiltration for recto-vaginal fistula

Fig 14 Infiltration for Le Fort operation (anterior)

Fig 15 Infiltration for Le Fort operation (posterior)

When the peritoneal reflection is reached injections are made before opening the peritoneum. Then with the finger in the peritoneal cavity as a guide, the broad ligaments can be infiltrated. About thirty cc or more of novocain are injected on either side. The marked blanching of all the tissues which have been injected guarantees not only painless but also bloodless operating (Fig 5, 7, 8, 9, and 10). In this series we had six cases (Table III-D).

Interposition and Fothergill operation. The same technic is employed here as for anterior colporrhaphy. In addition the vesicouterine fold is exposed behind the bladder and injected before being incised. The visceral peritoneum of the anterior uterine wall is infiltrated before being grasped by the Allis forceps to bring the fundus forward (Fig 8 and 9). We have done ten interposition operations, twenty-six Fothergill operations with amputation of the cervix, and

two modified Fothergill operations without amputation of the cervix (Table III-D).

Vaginal hysterotomy. We have had three cases in this group (Table III-D). The anterior and posterior walls and cervix are infiltrated as described above (Fig 5, 7, 10). Then the bladder is separated from the anterior surface of the uterus. The cervix is cut after making injections of the anterior lip and to the right and left of the midline. Further injections are then made on the anterior wall of the uterus and the incision is carried upwards (Fig 16).

Vesicovaginal fistula. Two cases were done (Table III-B). Infiltration of the vaginal mucosa and the bladder wall up to the submucosa. The area can be excised and sutured without pain (Fig 12).

Rectovaginal fistula. Infiltration of vaginal mucosa and the rectal wall up to the submucosa (Fig 13). Generally fistula cases are best done under some other

type of anesthesia, especially where operation has previously been performed

The female urethra is easily anesthetized by a film of cotton placed around the end of a probe and saturated with a five or ten per cent solution of novocain passed into the urethra and allowed to remain a few minutes

Caruncles are easily extirpated by infiltrating around and beneath them. The surface can be swabbed with a ten per cent solution for a few minutes at the point where the needle is to enter. Within a few moments the growth can be painlessly removed

It is important to note that in operating on the cervix and uterus, the pulling down of these parts to the vaginal outlet is attended with some discomfort, and should not be attempted where they are bound down by adhesions or fixed in the abdominal cavity. On the contrary, in cases where these parts are well-relaxed and freely movable, operation can be quite satisfactorily undertaken

The Le Fort operation for complete prolapse was performed on five cases (Fig 14 and 15) (Table III-D)

Results

Table I shows the various types of anesthesia used for vaginal plastic operations between 1925 and 1935. There were 4017 cases in all. The greatest number were done with nitrous oxide narcosis, 2849 cases or 70.9 per cent. Ether followed with 634 cases or 15.7 per cent, and local infiltration with 443 cases or 11 per cent. Other anesthetics were employed in ninety-one cases or 2.4 per cent. In this connection it should be kept in mind that it has been only within the past three years that local anesthesia has become popular with some of us. Chart I shows graphically the trend in our clinic

Table II gives a comparison of general and local anesthesia during this same period. There were 3926 cases. Ether was used in 634 cases or 16.14 per cent. Nitrous oxide was employed in 2849 cases or 72.56 per cent and local infiltration was used in 443 cases or 11.3 per cent. The apparent discrepancies in percentages in this table are due to the fact that the total number of cases is different from those in Table I

Table III gives a list of vaginal operations performed in this series. There

pressions, it is fair to state that each patient was then recorded as a new case under a new therapy, and microscopic and cultural examinations were repeated in detail. This procedure was followed in each case whenever the method of treatment was changed and accounts for the small number of cures compared with the total number of patients seen and treated. This protracted method of trial and error before arriving at the desired result in many cases, probably explains the failure of some patients to return to the clinic. However, so far as the choice of the best treatment is concerned, this proved an excellent way to demonstrate clinically the advantages and disadvantages of different methods now in common use.

Oral and injection treatments. The next method was suggested by the fact that the organism is a protozoan, and that the value of arsenic for its destruction is established. Sodium arsenate, one per cent in phenol, was administered three times a week intramuscularly, beginning with three minims and gradually increasing it to fifteen minims. Such a course required about one month, during which time weekly local examinations were made, with extremely disappointing results. There was no change in the patient's symptomatology and the organism remained active and vigorous. The associated organisms also remained unaffected.

In another twenty-five cases arsenic in the form of neoarsphenamine 5 grams and mapharsan 45 grams were given intramuscularly at weekly intervals. This method was tried because such striking results follow the use of salvarsan in cases of Vincent's angina. The end results after this form of medication were also disappointing, and toxic symptoms developed in too many instances to warrant its use for such a condition. There was no change in the activity of the trichomonads, in the patients' symptoms, or in the associated bacteria. Bismuth ten per cent in peanut oil as used in the Syphilitic Clinic at the Post-Graduate Hospital, was also given twice a week intramuscularly in these cases without any appreciable result.

Arsenic was further tried by oral administration in the form of Fowler's solution, given over a period of one month and in the usual dosage, but without any effect.

Recalling the recent outbreak of amebic dysentery and the favorable results following the oral administration of arsenic in the form of acetarsone and carbarsone in three and two grain capsules given three times daily for a period of ten days, this method was tried in a few cases. When no effects

were noted after the first course of treatment, additional doses were given. No alteration in local or cultural findings occurred, and since toxic symptoms appeared it was deemed advisable to discontinue treatment.

Local treatments with solutions. Innumerable varieties of local vaginal therapy have become popular during the past few years. It would be futile to review them all. Suffice it to say that most of them include a thorough cleansing of the vulva and vaginal mucous membrane, too often carried to the extreme of *unnecessary trauma*, which not only does not aid in the cure, but even *lowers the resistance of the tissues*.

In one series of cases the effect of mercury oxycyanide, 1:4000, was tried. It was used as a vaginal irrigation and instillation without apparent effect on the trichomonads, even after two weeks of treatment, and was then considered ineffective, as a trichomonocide. In other series merthiolate, 1:10,000, potassium permanganate 1:4000, clymacol 1:10,000, bichloride of mercury 1:2000—were all used as vaginal irrigations and instillations, giving the same number of treatments and with the same unsatisfactory results.

Vaginal treatments with powder and bladder instillation. Quinine in different form has been widely used and I tried it also. I had previously used it in a solution of quinine dihydrochloride one per cent, fifty c.c. as a vaginal packing and fifty c.c. as a bladder instillation. Fair results were obtained in these cases and since quinine is considered a parasitic poison, it was further tried in powder form as quinine sulphate. In all of these cases vigorous scrubbing of the vulva or vagina was omitted, all applications being made as gently as possible.

After irrigating and dilating the vagina with an occluding vaginal syringe and with plain tap water, the cervix and vaginal vault were carefully and gently dried with cotton. The vagina was then dilated and insufflated with quinine sulphate grs. XII using a Powdex vaginal insufflator. These treatments were given three times a week for two weeks. As in all other cases, a high power examination was made at the time of the last visit and weekly thereafter for three months before any patient was considered cured. If the organism was found at the last visit, she was considered still infected, and if not found then but within three months, the infection was regarded as recurrent. The foci not having been found, the same treatment was repeated with the addition of a fifty c.c. instillation of quinine dihydrochloride one

per cent in the bladder. In the first group of forty-five cases in which quinine sulphate grs XII in powdered form was used in the vagina without bladder treatment, fourteen (31 per cent) were cured, and thirty-one (69 per cent) were failures. In the second series of thirty-seven cases receiving both vaginal and bladder treatment with quinine, thirteen (35 per cent) were cured and twenty-four (65 per cent) remained infected. The conclusion was justified that quinine sulphate was not an effective trichomonocide. I also found that the patient was not relieved symptomatically as quickly as after the use of other medicaments, and that occasionally patients were sensitive to quinine either locally or constitutionally. A few patients developed small vaginal ulcerations or a cystitis which I attributed to the quinine.

Using the same technic, acetarsone, grs XV was insufflated and the bladder left untreated. In twenty-seven such cases there were fifteen (55 per cent) cures and twelve (45 per cent) failures. In another series, using acetarsone, fifteen grs in the vagina as an insufflation and ten grs in the bladder as an instillation, there were thirty-seven cases, of which twenty-six (70 per cent) were cured and eleven (30 per cent) failures.

In still another group of cases, I used arsenic grs XV in the form of cinquarsen, a pentavalent arsenic compound. There were twenty-five patients treated, with twenty-one (84 per cent) cures and four failures (16 per cent). In fifty-five cases cinquarsen, grs XV was used as a vaginal insufflation and cinquarsen grs VII ss or fifty c.c. of a one per cent solution, were instilled in the bladder. Fifty-three (96 per cent) were cured with two failures.

Blood chemistry. Because of the signs of toxicity after the use of quinine in the vagina and bladder, probably due to absorption and the patient's idiosyncrasy to quinine, the patients under treatment with cinquarsen were closely observed for such signs of toxicity as itching, acne, urinary complaints, and albumen or casts. As a further precaution, chemical blood analyses were made with the patient on an arsenic-free diet. The bio-chemistry department of the Post-Graduate Hospital made these analyses, using twenty to thirty c.c. of blood taken two days after the last treatment was given. The results of these tests estimating the arsenic in the blood ran from 0.2 to 0.8 mgs per one hundred c.c. of blood, an average of 0.43 mgs.

Relief of symptoms immediate. I found that cinquarsen in combination with an acid diluent afforded almost immediate relief of symptoms, particularly the foul discharge,

burning, and pruritus. This is probably due to a change in the pH of the vaginal secretion to more closely approach that of the normal, as the use of sodium bicarbonate as an alkaline medium did not allow such immediate symptomatic relief. I also believe that the endocervical glands, as well as the urethra or bladder, are likely sources of reinfection. I noticed that in twenty-five cases in which a primary cure had been affected, as well as some other cases in which routine high power examinations were negative on several visits, reinfection with trichomonads followed treatment of the cervix, such as cauterization or conization. After that I treated any coexisting disease of the cervix at the second and third visit, using a local anesthetic and cauterizing the canal and portio.

Due to the well-known clinical fact that the trichomonads become markedly activated immediately before, during, and after menstruation, and the cultural fact that human whole blood stimulates its development, all patients were treated regularly throughout the menstrual period if it occurred during a course of therapy.

To prove that the usual diluent in powdered mixtures and the popular douche medicaments were ineffective as trichomonocides, they were used alone in a number of cases. Sodium bicarbonate, boric acid, salicylic acid, zinc oxide, and sodium perborate were used as powder insufflations. Mercuric oxycyanide, potassium permanganate, sodium perborate, and bichloride of mercury were used as douches and instillations without benefit to the patients.

The bladder is often ignored as a possible focus of infection and is not treated. The seriousness of a trichomonas infection is frequently underestimated and treatment is carried out in a haphazard manner. Likewise, the husband is neglected as another focus of reinfection, as intercourse has not always been deemed a probable means of transmission. These factors, when considered collectively, are the chief causes of unsatisfactory results after treatment, and have a distinct bearing on the so-called "recurrent case." A totally different regime was therefore selected to discover the most effective medicament.

The results of treatment and the cures cited in this paper include only those cases free from symptoms and from the trichomonads throughout a three month period after treatment was discontinued. Many of these cures have been proved to be of four, five, six, eight, ten, and twelve months duration.

The treatment was confined to vaginal therapy for the first series. Each patient

was examined and treated three times a week for two weeks and returned for a check-up in one week, if still positive, a new course of treatment was begun, and if during that time trichomonads were found in the urine, the bladder was treated locally, however, if the urine examination was negative and the patient returned with the parasite still in the vagina, she was given six more vaginal treatments and the bladder was treated as well

Summary

1 A detailed personal history and a careful physical examination may reveal some causes other than the trichomonads to account for vaginal symptoms, urinary complaints, and nervous systemic disturbances, or menstrual irregularities

2 A routine high power examination of the vaginal secretion in all gynecological cases can establish the presence of *Trichomonas vaginalis* before extensive pathologic changes develop

3 The trichomonads will not always be demonstrable in the catheterized specimen of urine under high power examination, even though the urethra or bladder may be an additional site of infection

4 The majority of cases treated properly, consistently, carefully, and gently by vaginal dilatation, irrigation, and insufflation with a dry arsenical powder, in order to medicate the entire vaginal vault and cervix, three times a week for two weeks, can be permanently cured

5 Urethral or bladder involvement occurs in about twenty per cent of all cases and will cause the recurrence of vaginitis usually within one month, but the patient can be cured by another course of vaginal therapy, accompanied by bladder treatment

6 A few cases will require a second course of treatments three times a week for three weeks, and still a fewer number will need a daily treatment for two to three weeks. This is explained by the patient's lowered resistance to this particular infection, or to the high virulence of the strain of trichomonads harbored by the patient.

7 It is possible for operative procedures on the cervix to light up a dormant *Trichomonas vaginalis* vaginitis. For this reason the cervix should be treated early during the active treatment of

the trichomonas infection

8 If the menstrual period should occur during a course of treatment, the treatments should not be discontinued

9 Intercourse should be interdicted during a course of treatment

10 Other members of the family, especially the husband, must be examined in all cases of recurrence or reinfection

11 A careful follow-up of each patient must be made weekly for at least one month after the last treatment, and immediately following the menstrual period for at least three months, before a cure should be considered permanent

Conclusions

1 The *Trichomonas vaginalis*, a flagellate described by Donne in 1836, is found in the vaginal secretions of patients complaining of local and general symptoms definitely related to this organism

2 The trichomonads can be seen microscopically in a suspension in normal saline under high power dry magnification

3 The trichomonads can often be demonstrated in a catheterized specimen of urine from a patient suffering from vaginitis

4 The trichomonads may be demonstrated in the prostatic fluid of the male partner of the woman infected with the organism

5 The trichomonads may be demonstrated in the female members of the same family

6 The trichomonads are not dependent upon any one coexisting organism to produce the lesions seen in this condition

7 The other organisms present in the vaginal secretions with the trichomonads are the same before treatment as after the trichomonads have been eliminated

8 Enough conclusive evidence has been presented by many investigators to prove beyond doubt the pathogenicity of the *Trichomonas vaginalis* vaginitis

9 Elimination of the trichomonads from the vaginal flora will free the patient of the irritating vaginal discharge, itching or burning, urinary complaints will subside unless there is an associated chronic pyelitis, the menstrual cycle will become more normal, fatigue, nervousness, irritability, emotionalism, and pelvic

discomfort will disappear and the patient will again have a sense of well-being

10 In the female, the cervix, urethra, and bladder, and in the male the urethra, the bladder, and the prostate may be considered foci which account for the recurrence or reinfection in a number of female patients. The uterus and the rectum are not factors in reinfection or recurrence

11 The vaginal infection must be treated with a medicament which must be a protoplasmic poison, must have local penetrative power, and must be kept in close approximation with the vaginal mucous membrane in a dry medium for a

long period of time. The best medication found in this series having these properties was cinquarsen in conjunction with boric acid, and a suitable diluent to give body and to aid in its dissemination over the mucous membrane surface

12 The cervix must be treated in all cases and the bladder treated in all reinfecting recurrent cases

13 *Trichomonas vaginalis vaginitis* is a pathological condition caused by the flagellate, named by the French investigator Donne and is curable if observed, evaluated, and treated properly

PROFESSOR ARCÉ OF ARGENTINE A VISITOR HERE

New York has a distinguished visitor in Dr Jose Arce of Buenos Aires who arrived on December 15 and is a guest at the Metropolitan Club. Rarely among confreres in any land has a physician attained the eminence—in so many cultural fields and public welfare activities—that is allotted this outstanding leader from South America's progressive republic. As president of the Argentine Chapter of the Pan American Medical Association, professor of surgery at the University of Buenos Aires, rector of the University and senator of Argentina, Dr Arcé comes to give addresses on "Pan American Medicine" before chapters of the Pan American Medical Association at New York, Washington, Los Angeles, and San Francisco, also, to observe facilities for teaching graduate physicians in this country. While here, the Medical Society of the State of New York will confer honorary membership upon him.

On December 20, Dr and Mrs Joseph Jordan Eller held a reception at the Court-

house Tennis Club to enable him to meet representative citizens of the metropolitan area. Invitations numbering 800 were issued including those to prominent physicians and their wives, leading citizens interested in Pan American affairs, ambassadors of Latin American countries, their alternates, and all consuls general with their wives from those countries.

Receiving guests at the reception were Hon Dr and Mrs Don Felipe A. Espil, Ambassador of Argentine, Dr and Mrs Conrado Traverso, Consul General of Argentine, Dr Charles Gordon Heyd, President, American Medical Association, Dr and Mrs James Alexander Miller, President, New York Academy of Medicine, Dr and Mrs Charles E. Farr, President, Medical Society of the County of New York, Dr and Mrs Arthur Chace, President, New York Post Graduate Medical School of Columbia University, Dr and Mrs Floyd E. Winslow, Rochester, President, Medical Society of the State of New York.

TREATMENT OF FRACTURES OF THE FACIAL BONES

GERARD H. COX, M.D., F.A.C.S., *Glen Cove*

The structures commonly involved in fractures of the facial bones are the superior maxilla, the malar-zygomatic arch, and the nasal bones. Fractures of the superior maxilla vary from lesions of the alveolar process to fracture of the anterior surface of the body of the bone, extensive fracture of the nasal bones and brain case, associated with injury of the cranial contents. The bony orbit may be fractured and its margins or floor split into fragments, with injury to the eyeball, optic nerve or lachrymal duct. Again, the fracture may involve the nasal accessory sinuses, producing infection or obstructed drainage.

Some of these fractures naturally lie in the field of the rhinologist or rhinoplastic surgeon. Others are more appropriately treated by the dental or oral surgeon.

The rhinologist should take care of fractures of the nose, malar-zygomatic arch, orbital border or floor, anterior wall of the maxillary antrum, and fracture of the anterior and posterior walls of the frontal sinuses. On the other hand, fractures of the alveolus or extensive transverse fractures of the body of the superior maxilla require the services of the dental surgeon.

Just a word in passing in regard to the latter, viz., extensive transverse fracture of the superior maxillary bone where there is downward displacement. Here, as I have said, the services of a dental surgeon are essential. In these cases it is not advisable to resort to wiring the fragments. The best treatment is a case-jacket splint with Kingsley arms connected with a head cap on each side of the mouth. In edentulous cases the Kingsley arms can be used in connection with the patient's own vulcanite denture, if he happens to have one, and the latter is adapted as a splint.

Where the sinuses are involved in the fracture, in addition to restoring the nor-

mal contour of the face, we have the problem of adequate drainage. In a bad accident, our hands are full. The patient generally arrives at the hospital suffering from shock. In addition to reducing the fracture, there may be one or two wounds of the face to be sutured, to say nothing of involvement of one or more of the nasal sinuses in the line of fracture.

Fractures of the upper jaw and malar bone usually are the result of heavy, blunt, crushing blows, such as occur in automobile accidents where the face strikes against the body of the car, or, as happened in one of my own cases, where the patient was struck a heavy blow on the malar-zygomatic arch with a bottle in a fight. Fractures of the nose, on the contrary, are often caused by comparatively light blows.

While it is possible in cases of fracture to have one or more sequelae, such as purulent dacryocystitis, sinusitis, injury of the eyeball, malocclusion of the teeth, etc., it is astonishing how most patients, if the wounds are promptly sutured and the fracture reduced, recover without any permanent injury or bad sinus infection.

Fracture of the malar-zygomatic arch, before the extensive use of the automobile, was comparatively rare. For example, Kemper,¹ in 1902, in a survey of the world literature in the United States Surgeon-general's office found less than one dozen cases reported.

Roberts,² in 1928, found fifteen additional case reports, and added three of his own. Now, with the large number of motor accidents occurring daily, any surgeon connected with an active surgical service meets these fractures from time to time. During the past year I have had under my care four cases of fracture of the malar bone. One of these was associated with extensive fracture of the orbital margin, orbital floor, and anterior wall of the maxillary antrum.

This patient was treated by the Cald-

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 28, 1936*

Fig 1 Depressed fracture of the malar bone. From Scudder's "Fractures"

well-Luc incision I was then able to lift up the malar bone and floor of the orbit with my finger in the antrum. I endeavored to hold up the fragments by packing inserted in the antrum and brought out through a counter-opening in the nose. In this connection I may say that one of the standard text-books on fractures advises leaving the packing *in situ* for ten days. I do not believe this can be done, as a rule. In my own case, owing to the inflammatory reaction and swelling of the face, I was obliged to remove the antral packing at the end of forty-eight hours.

Just a word about the frontal sinus. When the radiogram shows fracture of the frontal sinus with cloudiness, and we suspect fracture of the posterior plate, external drainage is indicated, on account of the danger of meningitis.

One of my other cases was a depressed fracture of the malar bone, accompanied by fracture of the orbital margin (Fig 1, 2). The patient was a young man who was struck directly on the malar bone with a bottle. The blow crushed in the malar bone and considerable deformity resulted. I reduced this fracture under general anesthesia, with a periosteal elevator inside the mouth, which was pushed

up through a small cut in the mucous membrane opposite the bicuspid teeth into the zygomatic fossa, hugging the malar bone. With the elevator inside the mouth and a finger over the malar bone, I had no difficulty in restoring the normal contour of the face. No splint was necessary to hold the fragments in position. After the operation, I made a trip to the morgue to try out this operation more fully. Having obtained a cadaver, I fractured the malar-zygomatic arch with a blow from a hammer. I was amazed to find how much force was necessary to produce the fracture.

Using the periosteal elevator in the manner indicated above, I found that not only depressed fractures of the malar bone, but also fractures of the zygomatic arch, well back toward the condyle of the jaw, could be elevated in this fashion. I have no hesitation in recommending this procedure as a simple and reliable one.

There are several other operations for elevating fractures of the malar bone.

1. Matas' operation, which consists of running a silver wire around the zygoma, after passing a piece of silk on a Hagedorn needle under the bone. The zygoma is then raised and if necessary, can be held in place by tying the wire about a glass slide.

Fig 2 Method of reducing fracture of malar-zygomatic arch by passing elevator through the mouth and under the malar bone.

2 The open operation, where a small skin incision is made over the arch, through which a hook or corkscrew is used to elevate the bone

3 Gillies' operation Here an incision is made above the hairline in the temporal region and an elevator passed down along the muscle until the bone can be elevated

4 I have already spoken of the antral route, which I used in one of my own cases

The diagnosis of fractures of the malar-

suitable cases, fat or fascia lata may be employed

To properly treat fractures of the nose, it is necessary to bear in mind a few anatomical points

The nose is composed of a bony and cartilaginous framework

The bones comprise the two nasal bones, which articulate with each other in the median line and with the frontal bone

Fig 3 (Left) Recent fracture (Right) Same patient taken four days after reduction

zygomatic arch is often made by inspection and palpation The x-ray, if positive, is helpful Let us not forget that the radiogram is not infallible Only a few days ago, I saw a woman of eighty-nine years, the victim of an automobile accident, who had a depressed fracture of the lower margin of the orbit which did not show in the radiogram

It is well to bear in mind that we get one symptom in depressed fracture of the zygomatic arch, which is almost pathognomonic I refer to inability to open the mouth fully due to pressure of the depressed fragments of bone on the coronoid process of the lower jaw

In old injuries, with depression of the malar bone, orbital margin or anterior wall of the frontal sinus, rib cartilage may be used to build up the deformity In

above Each nasal bone rests on the nasal process of the superior maxilla, forming part of the lateral aspect of the nose The nasal septum lies in the midline, partly bone (perpendicular plate of the ethmoid) and partly cartilage The alar cartilages support the lower lateral structure of the nose

Recent fractures of the nose may be divided into linear, comminuted, and depressed fractures Like fractures elsewhere in the body, they may be simple or compound They may communicate with the external air either through the nasal mucous membrane or through the skin

Fractures of the nose may involve the nasal bones, the nasal processes of the superior maxilla, the nasal spine and the articulation of the nasal bones with

the frontal bones. There may be a fracture-dislocation of the septum or the lateral cartilages may be torn away from their bony attachment.

In general, there are two types of fracture. In the first, the blow is received in an anteroposterior direction, and the nasal bones are driven backward like a wedge, often spreading the nasal processes in a lateral direction.

see a gross deformity resulting from the fracture, or you may be able to gently feel a depressed or broken fragment of bone. X-ray is naturally of great value. Its use, in my opinion, should not be substituted for a careful clinical examination. A short time ago in one of the large New York hospitals, I saw a sixteen-year-old boy with a depressed fracture of the nasal bones. There was also some separation of

Fig 4 (Left) Recent fracture. (Right) Same patient three weeks after operation. Fracture reduced with local

Where the traumatism is received from one side, as in a right-handed blow with the fist, the left nasal bone and perhaps the left nasal process are depressed. On the opposite or right side, on the contrary, the nasal bone is forced still further to the right, and a convexity is produced. The nasal septum will probably be dislocated or fractured at the same time.

The diagnosis of a fractured nose is often easy and may be perfectly evident from inspection alone. Other times, if there is considerable swelling before you see the patient, the diagnosis is not so simple. I personally do not take hold of the nose and manipulate it until I can feel crepitus. This is not pleasant for the patient and the latter may with perfect propriety object to the procedure. If you wait until the swelling subsides, you may

the alar cartilages from their bony attachment. For some reason, the x-ray failed to show the fracture. If I had not happened to examine the patient, he would have lost his opportunity to be treated, because the intern was depending upon the x-ray report rather than upon the clinical examination.

Now we come to the question of the proper treatment to pursue in a given fracture. This naturally is for the clinician to determine. The radiogram cannot be relied upon to inform you as to the position of the fragments in most instances. When the swelling goes down, if the patient looks well and the bones are in good alignment, leave him alone. If he has a deformity, fix his fracture. Never mind what the x-ray report says.

Fig 5 (Left) Old deformity or "saddle-nose," due to fracture several years ago (Right) Same patient after refracture and narrowing, followed by rib cartilage transplant operation

Anesthesia

There is no doubt of the fact that most fractures of the nose can be reduced by local anesthesia without much discomfort, or, if you prefer, with general anesthesia. The latter has the advantage that the operator is better able to immediately judge the results of his work, as there is no distortion of the soft parts, such as produced by infiltration.

I always tell our interns not to operate upon nasal fractures with gas anesthesia from which the patient may come out before the fracture is fully reduced. If general anesthesia is decided upon, use gas-ether or some anesthesia where the operator will not be hurried.

If local infiltration with novocain is employed, we should also pack the nose with pledgets of cotton saturated with ten per cent cocaine.

In general, I may say that I prefer general anesthesia rather than local, where there is considerable edema and ecchymosis of the soft parts.

Recent fractures of the nose, if seen early, before swelling of the soft parts supervenes, should be operated immediately.

If not seen early, and there is too much

swelling, it is best to wait for the edema to subside. If the patient is brought in suffering from shock, we are forced to postpone operation until he reacts. One woman, with a bad fracture of the nose, leaked cerebrospinal fluid through the cribriform plate and nose for several weeks. The surgeon in charge very wisely did nothing. The patient recovered, and a number of months later the deformity was corrected by plastic surgery.

The technic which I employ for the correction of recent fractures is as follows. Use a general or local anesthetic, take plenty of time, use as few instruments as possible, and do not employ any more force than is absolutely necessary. I find I can reduce the large majority of recent fractures with a small submucous periosteal elevator and my thumb. The elevator is used to raise the depressed fragments of bone, and the thumb is employed to exert pressure over the convex side of the fractured nose to force the fragments back into the median line. Sometimes the flat handle of a rasp, protected by a piece of gauze, is held over the displaced nasal bone and a sharp blow with a mallet is administered. Usually, if the external deformity is corrected, the septum snaps back into position. If not, it

may be necessary to use an Asche forceps

It is not always necessary to immobilize a fractured nose after reduction. If the deformity is a slight one, and the displaced fragment of bone snaps back readily into place, it is often possible to dispense with a splint. In the majority of instances, however, some form of immobilization is advisable.

The simplest is a bandage roll on each side of the nose, held in place by adhesive plaster. Moulded copper splints (20 gauge sheet copper) have been extremely useful in my hands. Some prefer to use red dental moulding material shaped to fit the nose, which, like the copper, is held in place by adhesive plaster.

Watson-Williams of London uses a triangular piece of silver wire introduced within the nose to hold up the depressed fragment. Carter³ has devised a bridge splint, and Gillies a splint attached to the teeth. One other which should be men-

tioned is Joseph's splint with leather head band and arms running down to one or both sides of the nose. These arms are adjusted by thumb screws.

Old lateral deformities of the nose require refracture and narrowing by the intra-nasal method, while depressed fractures (saddle nose) are usually treated by one operation to straighten and narrow the nose, and a second operation to build up the depressed structures by a rib cartilage transplant, which is usually taken from the patient's seventh, eighth, or ninth ribs.

The accompanying illustrations, show illustrative cases both before and after operation (Fig 3-6).

Discussion

DR. JAY DASHIELL WHITMAN, *New York City*—The injuries to the bones of the face about which Dr. Cox has spoken so completely are all caused by direct violence.

When I first studied medicine a fracture of the malar bone was called a "bicycle riders fracture." Since the advent of auto-

mobiles and airplanes much greater force is applied to the face in accidents through a fall from a bicycle and as a consequence, fractures of the bones of the face are usually attended by complications. Among the complications are shock, hemorrhage, fracture of the skull, concussion of the

Fig 6 (Left) "Saddle-nose" deformity (Right) Same patient after rib cartilage transplant.

rain, fractures of the jaw bones, and extensive laceration of the soft tissues

The reduction of a fracture of the malar bone, which is always a depressed fracture, can be accomplished by the external use of a traction screw but the method described by Dr Cox of replacing the bone through the buccal route is preferable. Should the outer nasal wall be comminuted, as is often the case, Dr Cox's method is of especial advantage in replacing or removing the displaced fragments. When the depressed malar bone has once been replaced no appliance or dressing is needed to retain it in position.

Fractures of the zygoma are usually uncomplicated. There is always an inward displacement of the bone. This I believe is best corrected by a small hook introduced through a tiny skin incision. Reductions through the mouth might cause an infection of the infratemporal fossa. Fracture of the zygoma does not interfere permanently with the movement of the jaw even when it is not reduced. Fractures of the orbital margins are usually complicated by fractures of other bones especially the nasal bones and skull. They are usually accompanied by extensive laceration of the face and hemorrhage in the orbit. The deformity is corrected by a hook or screw externally. When this is not successful an incision similar to the Caldwell-Luc incision is made and the reduction is made directly. When the fragments tend to fall out of place they may be perforated in two places and No. 22 silver

wire carried through the perforations and twisted to coapt the fragments. It is not necessary to remove the wire after union has taken place.

On my nasal plastic service at Bellevue Hospital we have operated on several hundred, recent and old fractures of the nose and have had an opportunity to try out many old and new ideas. It is not possible to discuss this briefly.

When the nasal and facial bones are badly comminuted and extensive laceration of the tissues is present one is tempted to remove the loosened and misplaced bone fragments. This temptation must be resisted. The fragments should be replaced and held in their correct position by fine catgut sutures through the periosteum. Special attention should be given to the lining mucous membranes for the final cosmetic effect will depend on the proper restoration of the mucous linings and the bony structures as much as on the attention paid to the skin covering.

Where there has resulted a loss of bony support after extensive injuries, fat and fascia or rich cartilage grafts will improve the result. My preference is for small flat pieces of rib-cartilage. Such grafts are especially useful in restoring depressions of the orbital margin, the nose, and the forehead. When the frontal sinus has been obliterated by a radical operation, small flat bits of cartilage inserted under the skin will give a good cosmetic effect.

ETHICS THE SAME IN ALL TONGUES

The problem of medical advertising in a polyglot city like New York has been greatly complicated by the foreign language press, says the *Medical Week*. Following the custom of their country of origin, many foreign born physicians catering to patients of their own nationality have been accustomed to advertise in newspapers published in their native tongue. In Europe this is not an uncommon practice. In the United States it is a violation of the code of professional ethics.

Such infractions, springing from long established custom, might not have been serious per se had they not been aggravated in many cases by the nature of the advertising employed. Very few of the foreign language newspapers restrict their advertisers and more than one doctor went the limit in proclaiming his skill and promising cures.

In an attempt to curb exaggerated and misleading advertising without striking too severe a blow at national custom, The Medical Society of the County of New York for a period of years has waived some of its restrictions on advertising for the benefit of foreign born physicians in their dealings with compatriots. Notices in the foreign language press have been permitted, provided they confined themselves to the name, address and specialty of the advertiser.

It is time, however, for foreign physicians who desire to remain in good professional standing to relinquish these special privileges and abide by the same rules as govern the rest of the profession. Henceforth the Principles of Professional Conduct will apply equally to all practitioners, no exceptions will be made in favor of the foreign language press. It is hoped that the new ruling will be promptly and strictly observed.

ASPIRATION OF WOODEN TONGUE DEPRESSOR

Followed by Purulent Pneumonitis

HENRY P. SCHUGT, M.D., F.A.C.S., *New York City*

The following case, because of its unusual nature constitutes a warning to the profession to be alert to the possibility of the aspiration of a foreign body into the bronchial tree during general anesthesia. Search of the literature reveals only one case of a foreign body similar to that described in this report, having been removed from the trachea.¹

J.L., white, male aged twenty-nine was admitted to the hospital with the diagnosis of perforated gastric ulcer. His condition was so alarming that an immediate operation was imperative. While under general anesthesia it became necessary to insert a pharyngeal breathing tube, and the anesthetist attempted to open the patient's mouth with a wooden tongue depressor. At this instant the patient made a violent gagging effort the tongue blade was broken into two pieces, and the distal fragment disappeared. It was assumed that the missing part had been coughed out by the patient but despite careful search of the operating table and room the fragment could not be found.

Two days later the patient's temperature rose to 103.4° F. Clinical examination of the chest revealed no evidence of pneumonia at that time. Four days after the operation the patient began to cough up a brownish sputum and dullness became evident to percussion at the right base of the lung, accompanied by coarse râles and bronchovesicular breathing. Radiographs showed consolidation of the inner zone of the right lung. A diagnosis of pneumonia was made and appropriate treatment instituted. Radiographic studies of the chest revealed no foreign body. When the pneumonia failed to resolve after two weeks the author was asked to perform a bronchoscopic examination. When this was done a large portion of a wooden tongue depressor (Fig. 1) measuring 6.5x1.7 cm. was found in the lower trachea resting on the bifurcation. The foreign body was removed without difficulty.

Although the patient's temperature came down slightly it remained around 100-101 degrees. His general condition continued to be poor. Physical and radiographic

examination revealed a purulent pneumonitis in the right lower lobe. A second bronchoscopy was done and a considerable amount of purulent material was aspirated from the right lower lobe. Another rise of temperature to 103 degrees in the afternoon continued for one week during which time a right-sided pleural effusion developed. Thoracocentesis obtained a small quantity of sterile fluid. A transfusion of 500 cc of whole blood was given. During the following twenty-one days the temperature gradually came down to normal. The patient showed no further signs of pulmonary infection and he left the hospital eight weeks after admission, in excellent condition.

Fig. 1 Wooden tongue depressor (6.5x1.7 cm.) removed from trachea.

Comment

Study of this case emphasizes the importance of immediate bronchoscopy in postoperative pulmonary complications such as atelectasis and suspected foreign body. While this is well-known to bronchoscopists it is not sufficiently realized by the general medical profession. The delay in this case was considerable, but fortunately, it was not followed by some of the grave sequelae too often noted, such as chronic lung abscess, bronchiectasis or death from pneumonia or chronic sepsis.

TRANSFUSION SYPHILIS

MORTON W WILLIS, M D , *New York City*

The following case is reported because it indicates that syphilis can be transmitted by blood transfusion even though the donor has a negative Wassermann test and has previously received six intravenous injections of an arsenical preparation

Mrs A G had received prenatal care at the Metropolitan Hospital Prenatal Clinic, where her Wassermann test was found to be negative

On September 28, 1935, she was admitted to X— hospital during the third stage of labor because of retained placenta, vaginal hemorrhage, and shock The Kahn test on her blood was negative

The next day, a transfusion of 350 cc of blood was given, the donor being a friend of the family, S C No record has yet been found of a Wassermann test having been done at the X— hospital on this donor before the transfusion was performed His Wassermann reaction was reported by the Department of Health on September 28, 1935, as plus-minus, and on October 9 as negative

On January 28, four months after the transfusion, Mrs A G entered the Mount Sinai Hospital because of pain and tenderness in the lower cervical and dorsal regions in the back which she had had for about a week Examination revealed a generalized lymphadenopathy and a palpable spleen The blood Wassermann was four plus and the Kahn test on the blood two plus Blood examination was as follows Hemoglobin fifty-eight per cent, red blood cells 3,570,000, platelets 240,000, white blood cells 4,100, non seg five per cent, seg sixty-four per cent, eosinophiles two per cent, lymphocytes twenty-three per cent, monocytes five per cent X-ray of the spine was negative A biopsy of a supraclavicular node was reported showing inflammatory hyperplasia

Because of the strongly positive Wassermann reaction, it was suspected that the general lymphnode enlargement might be due to syphilis The patient was therefore given a provocative injection of neoarsphenamine 0.2 grams on February 8 Two days following the injection, she developed a typical copper-colored macular eruption on the trunk and upper extremities which was diagnosed by Dr I Rosen, chief derma-

tologist of the hospital, and Dr L Chargin, as a secondary syphilitic eruption The rash gradually faded in the course of the next four days Antiluetic treatment was given. The patient received both neoarsphenamine and bismuth

The history of the donor is as follows On September 9, 1935, he applied to the Board of Health clinic on Centre Street because of a small penile ulceration and a history of having had intercourse with a prostitute. On the same day, the dark field examination was found to be positive for spirochetes and treatment was initiated Examination revealed inguinal adenopathy in addition to the penile ulceration There was no eruption on the body or on the mucous membranes 0.02 grams of mapharsen was given on September 10, and 0.06 grams on September 14, 18, 21, 25, 28 On September 14, the Wassermann was reported as anti-complimentary On September 28, it was reported to be plus-minus and on October 9, negative The injections of mapharsen, 0.06 grams were continued every three or four days after September 28 until twelve doses were given Then nine doses of bismuth were administered The Wassermann became positive, four plus, on December 4 after the fourth dose of bismuth had been given Although injections of 0.06 grams of mapharsen have been alternated since then with injections of bismuth, the Wassermann reaction still remains four plus

This case of transfusion syphilis is reported because of its unusual importance The donor's blood was still infectious in spite of the fact that he had six previous injections of an arsenical preparation He was in the primary stage of syphilis and his blood Wassermann was plus-minus on the day before the transfusion and was reported as negative eleven days after the transfusion

The experience demonstrates that a negative Wassermann reaction on a blood donor is not sufficient to eliminate the possibility of active syphilis and of a spirochetal bacteriemia In addition to the Wassermann test, the donor should be asked concerning syphilitic infections

From the Mount Sinai Hospital, service of Dr George Baehr

SPECIFIC THERAPY IN RHUS DERMATITIS

HERMAN SHARLIT, M D and BEN A NEWMAN, M D, *New York City*

From the Departments of Dermatology and Syphilology, New York University College of Medicine and of Bellevue Hospital (Service of Dr Howard Fox)

The high incidence of Rhus dermatitis in this locality, the extreme discomfort to the victim, with resulting economic loss through incapacity, justifies persistent search for an effective remedy. In keeping with modern trends, and experience with allergic phenomena, sporadic reports covering approximately twenty years have dealt with the use of Rhus leaves and their extracts, both as a curative remedy and an immunizing procedure. Two facts stand out as a result of these efforts (1) that occasional helpful preparations have been made and (2) that present available Rhus preparations, as supplied by manufacturing pharmacists are quite generally useless or undependable. The first warrants and the second compels a further effort to prepare a useful Rhus extract for the treatment of Rhus dermatitis.

Duncan¹ attempted popularization of the ancient folk remedy of chewing Rhus leaves. Strickler² recommended the oral administration of the tincture of Rhus leaves. Shamberg³ offered the hypodermic use of this tincture. These somewhat promising reports were met with a "failure to confirm" in the publication of Krause and Weidman,⁴ and this not alone for treatment but for immunization as well. However, a current publication by Molitch and Poliakoff⁵ reports successful immunization therapy by the use of an extract made according to the directions of Spain and Cooke.⁶ A new departure came with the introduction of an oily solvent for the Rhus substance. Clock,⁷ using almond oil, reported it more potent than alcohol extracts and nontoxic, with the added advantage of being painless on injection. Gowen's⁸ publication was essentially in confirmation of this. It is of interest to note that attempts at immunization via baths containing Rhus extract

were tried and reported.

Dermatologists, after a liberal experience with such products as based upon the above reports, were quite generally agreed that no reliance could be placed in them in the treatment of Rhus dermatitis. Special attention, however, must be paid to the report of Spain and Cooke in 1927. They undertook to circumvent the evident instability of Rhus extracts by making extractions in the complete absence of water, using absolute alcohol as a solvent. In the light of our own experience, we emphasize the importance of this contribution, realizing, however, that this is but one of several conditions underlying the preparation of a satisfactory, reproducible extract. We, too, are not as yet convinced of the complete adequacy of the method we employed in the preparation of our active extract. We include it, however, as a matter of record. Apparently it differs little, if at all, from that outlined by Spain and Cooke.

Our effective extract was prepared as follows:

Freshly gathered ivy leaves were thoroughly dried at a temperature of 50°C. These dried leaves were broken up in a coarse mesh sieve, thus sifting out for elimination bits of twig and mid rib. Ten gms. of leaves were extracted with one hundred cc absolute alcohol for seventy-two hours at room temperature, and filtered. This filtrate was kept as stock solution.

We selected for treatment only such patients in whom the clinical diagnosis of Rhus dermatitis was definite and in whom the condition was severe or moderate. The severity in all cases was such as to show involvement at least of both upper and lower extremities, with edema, vesiculation, and intense pruritus. The patients in our group ranged in age from six to sixty-two years. No topical appli-

cations were permitted during the treatment. At the first visit each patient was given, in addition to the first injection, a patch test with the ivy extract, in a concentration used in the treatment. The treatment consisted of a hypodermic injection into the deltoid region, with a $\frac{3}{8}$ inch needle, on each of three successive days. The extract used was a 1:1000 dilution (1% of stock solution), in absolute alcohol, dosage 1/10 c.c. A local burning sensation, lasting less than one minute was the only reaction to the injection. No local reactions were noted with the exception of an occasional slight erythema about the point of injection. Eight patients in this group were used as controls for an evaluation of the effect of the solvent. They were given injections of 1/10 c.c. absolute alcohol. Eighteen patients were treated with an absolute alcohol extract of ivy leaves in like dilution and in similar manner, but from a preparation suspected, through previous patch testing, to be ineffective.

It is to be understood that by effective therapy we refer to the cessation of symptoms and stoppage of further spread of the inflammatory reactions. Where successful treatment ensued, amelioration set in after the first injection. Table I gives a statistical picture of our results. Of seventy-four patients treated with the effective extract, sixty-three received complete relief in four days, eleven failed of such relief. No aid came to the eight control subjects treated with the absolute alcohol and none to the eighteen treated with the ineffective extract.

These results are definitely and unequivocally proof that an ivy extract can be made that is curative of Rhus dermatitis. The results of the patch tests made after the usually approved manner and applied for twenty-four to forty-

eight hours, gives, it seems to us, some directive definition of the type of extract that may be expected to give satisfactory results in treatment. Of the sixty-three relieved cases all gave a positive patch test. Of the eleven unrelieved cases, by way of the effective extract, six gave a negative patch test. Further, of the eighteen unrelieved patients treated with the ineffective extract, none gave a positive patch test with that extract. It would appear that the effective extract should contain a dermatitis-causing substance, a "dermatogen," if word coinage is still permissible. That this "dermatogen" is identical with the causative principle of Rhus dermatitis is only presumptive but immaterial. The concept "specificity" in relation to therapy is not necessarily referable to any chemical homology between irritant and its therapeutic antidote. Specificity may just as appropriately be applicable to the source of the therapeutic agent with little, if any, reference to the chemistry of that agent.

For the moment it might be best to reserve this latter meaning for the specific therapy herein discussed. Concededly, immunization therapy would require, as we see it, a stricter definition of specificity. Indeed, if the term "specific therapy" is to avoid complete emasculation, it should, as referable to immunization therapy, apply definitely to the use of chemical units identical with those causative of the disturbance for which immunization is sought.

Aside from some uncertainty as to the exact position to be taken with respect to the definitive features of the term "specific," as applied to dermatologic therapy, a healthy skepticism should prevail concerning the "specific" nature of many therapeutic procedures that are

TABLE I

Number of Patients	Type of Extract	Number of injections	Dosage	Patch Test	Results on Fourth Day
63	Rhus Ext. effective	3	{ 0.1 Cc 1-1000 dilution	Positive	Complete relief of symptoms
5	Rhus Ext. effective	3	{ 0.1 c.c. 1-1000 dilution	Positive	No relief of symptoms
6	Rhus Ext. effective	3	{ 0.1 c.c. 1-1000 dilution	Negative	No relief of symptoms
18	Rhus Ext. ineffective	3	{ 0.1 c.c. 1-1000 dilution	Negative to ineffective extract	No relief of symptoms
8	Absolute alcohol	3	{ 0.1 c.c.	Positive	No relief of symptoms

apparently deserving of such identification. A fundamental weakness in the whole groundwork of allergic studies has been a lack of standardization of the method of preparation of the testing and treatment materials applied in the field. Until this all-important defect is remedied, the concept "specific" will remain unsatisfactorily definable.

Thus, in the matter of Rhus extracts, uncertainty in the matter of adequate methods of preparation has left our clinical experience without meaningful interpretation. Our report can at least be accepted to establish the fact that an effective therapeutic extract can be made. But what, to us, is of greatest significance and what most justifies this presentation, is the fact that but slight variation in

the technic of preparation meant the difference between a therapeutically effective product and a practically useless one. The problem remains, what are the precise conditions for the preparation of an effective extract. We hope soon to be afforded the opportunity to attempt a solution of this problem.

DO HEALTH WORKERS IGNORE ACCIDENTS?

The tendency of public health officers to concern themselves solely with the problems of diet and contagion, to the neglect of external causes of disability and death, is deplored in a statement issued by Dr. Edward S. Godfrey, Jr., State Commissioner of Health.

Referring to the increase in deaths from accidents in contrast to the decrease in the death rate from infectious diseases, Dr. Godfrey asks what the net gain could be when a child, who has been saved from death by regulation of his diet, eventually pulled a stewpan of boiling water off the stove and suffered a fatal scalding.

"What use to protect him against diphtheria when he is to be killed by an automobile?" Dr. Godfrey inquires.

"What impresses me," Dr. Godfrey says, "is that few, if any, health officers or health departments are displaying any interest in the prevention of injury and death from accidents. They are content that the statistics shall be tabulated and published, leaving prevention entirely to other agencies or to the will of God.

"There have been none to make the health officer feel any consciousness of the obligation to act, none to direct his thinking along preventive lines, none to point to the need for further information of the kind that will enable him to meet the problem."

Dr. Godfrey expressed the belief that health departments had their greatest responsibility and opportunity in the field of home and public accidents.

By studying individual public accidents, by plotting them on "spot" maps and by discovering common hazards, he said, much influence could be brought to bear for the removal of such hazards, just as health departments influence the removal of the dangers of polluted water supplies.

"With respect to home accidents, the opportunity and responsibility are more direct," he added. "Deaths from this type of accident almost equal motor vehicle accidents in the county as a whole and in some States exceed them. While the death rates from automobile accidents have risen, those from industrial accidents have fallen and those from home accidents have remained essentially the same.

"No one is in a better position than the public health nurse to note the physical hazards of the home, the personal habits that contribute to accidental death and disability. Parents are instructed how to feed, clothe and clean their children, in the importance of avoiding contagion, in the need for certain immunizations. It is high time that health departments take an active part directly and indirectly in the prevention of death from external causes."

ROLE OF THE PATHOLOGIST IN THE NON-TEACHING HOSPITAL

THEODORE J. CURPHEY, M.D., *Brooklyn*

This title is somewhat of a misnomer. By the non-teaching hospital is meant one not connected with a university, rather than one that does not engage in teaching. A typical hospital of this nature is staffed by men doing general work for the most part, with a fair number of men trained in the specialties. In the main, although the medical services given the individual patient are satisfactory, the clinical material is very seldom utilized to the fullest for the training of the visiting staff and intern personnel. The result is that the bulk of the hospital staff by virtue of the lack of organized facilities for the advancement of their own medical knowledge, never quite utilize fully their medical opportunities in the institution. It is in such a group that the pathologist will find an excellent opportunity for service, and it is the purpose of this communication to outline possible lines of development towards the attainment of this end.

For the pathologist to serve such a group efficiently, it is obligatory on the part of the institution to employ a man who is able to spend the major part of his time there. The present day arrangement prevalent in many hospitals, whereby the pathologist is largely a nominal head of the department working on a short part-time basis and without the use of resident or assistant pathologists in the institution is to be decried. Hospitals having such a working arrangement with a pathologist, based largely on the matter of economic consideration, are pursuing a "penny wise, pound foolish" policy, and the pathologist working under such conditions is found to be a poorer servant to his group on both medical and economic grounds. All of us know the type of pathologist who covers three or four hospitals in his stride in the course of his working day, and those of us who at one time or another, because of economic needs, have had to do this, know how ineffective and inefficient our efforts often are.

Allowing then that the institution is able and willing to provide for the economic security of the pathologist, thus permitting him to devote enough time to the problems of the group, the usefulness of the individual becomes at once evident. One of the first functions of such an individual should be the establishment of a laboratory organization that gives prompt and accurate service to the medical staff. In building such a service, as much attention should be paid to obtaining the confidence and good will of the medical staff as in carrying out the actual laboratory tests. The ultimate expression of this cooperative relationship will have been reached when a staff member, obtaining a laboratory report at variance with his clinical expectation, will be willing to concede that the laboratory is not in error, and that it is time to reinvestigate the case with another diagnosis in mind. For him to come to this opinion, he will have to have been gradually conditioned by previous experience with his laboratory staff as to their accuracy, sincerity, and helpfulness in the past. Too often in the non-teaching hospital especially, the effective assistance of the laboratory is lost because of the subconscious distrust and feeling of uncertainty that the clinical staff holds for the laboratory report. The consciousness of having obtained the confidence of the clinical group and the desire not to lose it offer one of the greatest driving forces to the pathologist in his hospital work.

There is another and more personal relationship of vital importance, if the pathologist's efforts are to be effective in his group. This is the appreciation by the clinical staff of his desire to be impartial and impersonal in the course of his work in the hospital. With due regard to the danger of overemphasizing the importance of the position of the pathologist in the hospital group, in many instances he functions as the court of final appeal in the case. This is perhaps more fre-

quently true in the field of surgical pathology where he is often called upon to pass opinion as to whether the structural changes present are sufficient to substantiate the pre-operative diagnosis of the lesion. In doing this he must be encouraged by the attitude of the staff to express the truth as he sees it. His usefulness, and more important still his position, should not be jeopardized by his adverse opinion, but there are hospital groups which have threatened the pathologist with the loss of his position because of his refusal to label as appendicitis, the histologically normal-appearing appendix.

Similarly, his function as an integral part of the clinico-pathological conference is one in which a fair-minded man can offer valuable help to his hospital group. It is first of all important that he be reasonably familiar with the difficulties in clinical diagnosis and not abuse his privilege by being unjustly critical after he has the benefit of the autopsy findings in the given case. Provided also that he makes the effort to correlate the clinical history with the autopsy findings, his expression of opinion should be accepted as his impartial view and should not have to be modified by the demands of the situation, as to whether such an opinion is apt to offend the members of the clinical group. We are all familiar with the situation where the pathologist has to exercise unnecessary reserve in his expression of opinion because of the undue sensitiveness of certain members of the staff to anything that savours of criticism. Happy indeed is the pathologist who finds himself in the environment of a non-teaching hospital able to express himself fearlessly on such matters as the "chronic" appendix or gall-bladder, or those errors in judgment that not infrequently lead to the autopsy table!

Another important function of the pathologist in the non-teaching hospital is that of entering actively into the utilization of the clinical material of the institution for original investigation. So many pathologists, because of their temperament and their training, exhibit some aptitude for clinical research. Similarly, in almost every hospital there will be found a sufficient number of the attending or intern group who have still retained or have developed some scientific curios-

ity. These men, by virtue of the greater demands on their time that clinical practice necessitates, are able to devote much less actual working time to investigative problems than the pathologist. If the latter attempts to provide them with stimulation, and also actual help, by placing technical assistance at their disposal, it is often a relatively simple matter to start some form of investigative work in the hospital. Such a policy, while often creating more work for the laboratory staff, incidentally acts as a powerful deterrent to its staff members from becoming mere routine workers, and forestalls the dissatisfaction that often comes to the more ambitious workers who are allowed to fall in the rut of common laboratory routine. Moreover, the psychological effect of such an effort on the other members of the clinical staff must not be lost sight of, as the power of emulation and imitation is an influential force in the smaller medical groups.

Perhaps one of the major functions of the pathologist in a hospital not connected with a university is his opportunity to interest himself in the activity of the intern staff. It seems that too little attention has hitherto been paid to this valuable arm of the medical group in non-teaching hospitals. There seems to be little realization as to the drastic change the recent medical graduate faces when he embarks on his training in the hospital, preparatory to practice. Unless his university training has been unusual, he starts in the hospital with a large assortment of medical facts which he, subconsciously at any rate, has come to regard as having almost mathematical accuracy. Coupled with this he is likely to lack perspective as to what are the really important features of his medical education. Often, too, if he has been trained in a school that tends to overemphasize the importance of laboratory investigation in the diagnosis and treatment of disease, he is apt to think that the matter is simply one of passing the patient and his excretions through the laboratory hopper and having them emerge with an accurate diagnosis at the other end of the machine. He soon comes to realize in his hospital work that many of the attending staff, especially those of the older school, use entirely different methods and thereby

cure their patients. If he finds that even after using his modern methods the diagnosis is often in doubt and that patients frequently die in the face of a seemingly good prognosis, good, that is, according to the mathematics of the laboratory, or better still, recover, often without any diagnosis at all, then he is at a loss to find himself, largely because of the big gap between his teaching in the university and the university hospital on the one hand, and the practical demands of a hospital life on the other. Such an individual with no help from the more experienced men in the clinical group, fights a losing battle for some time, finally succumbing to the odds against him, and is apt to become at the end of his internship a mediocre worker, lacking in the qualities of observation and deduction, and current literary knowledge, becoming a man on the threshold of medical practice with ideas colored by a desire to succeed largely through his political and social contacts, in preference to the more virile qualities of accurate training, clear thinking, and courage. The result is that a paradoxical situation now exists, in that year after year many men are being graduated from the universities imbued with a sense of medical idealism and provided with highly developed technical training, and are passing through hospitals of the type above described, finding themselves at the threshold of practice with what amounts to a great spiritual and mental loss, the result of the intervening denervating influence that the so-called non-teaching hospital provides. Such a series of events can but lead to the gradual deterioration of the ideals and technical qualifications of the practitioner of medicine.

One of the major aims then of the pathologist in such an institution should be in the direction of stressing to the intern staff the importance of careful clinical study apart from the laboratory aids. He should be able to show that a well-taken clinical history, coupled with sound clinical observation in conjunction with a minimum amount of laboratory work is frequently all that is necessary for the intern to arrive at the correct diagnosis and the proper management of a given case. To inculcate the idea of economy of laboratory work it is necessary for the pathologist to possess and

develop his clinical training and to be in close contact with the case material in the hospital, and to actively discourage unnecessary laboratory tests. To this end, too, the intern should be given a short period of training in the laboratory, during which time he will be able to see for himself how much unnecessary work is performed on patients.

Another function of the pathologist in such a hospital is to point out the need to the intern staff and often to the attending staff, of close observation of the progress of the individual case under treatment. So frequently a pathologist is called upon to perform an autopsy on a patient dying from an unusual or interesting disease, only to find that the clinical interest had ceased following the establishment of the working clinical diagnosis, with little or no clinical data in the intervening time between the diagnosis and death. It is the careful observation of the changes in the clinical picture during the progress of the disease, that is of inestimable value to the intern in his training, and he should be encouraged to write clear brief notes on the progress of his cases.

Another function of the pathologist, one far removed from his office, and one which rightly belongs to the attending clinician, is the attempt to impress the intern with the need for instituting rational treatment in the individual case and to check his enthusiasm in the use of therapeutic agents whose only recommendation is that they are new. The intern should be made to offer sound reasons, on such occasions as on ward rounds, clinico-pathological conferences, etc., why various therapeutic procedures have been ordered by him. This gradual process of training during his stay in the hospital, will undoubtedly make him skeptical of many of the newer therapeutic agents in vogue at the present time, and besides making for a sounder medical reasoning will help also to protect the patient's economic state.

The pathologist's interest in the intern's problems may be further stimulated by means of the clinico-pathological conferences that are common in every hospital. Such conferences should be essentially sessions in which the interns are encouraged to voice their opinions and their reasons for diagnosis and treatment of

their patients Too often this is not the case, the intern being nothing more than a passive bystander in the conduct of these conferences In order to encourage him to take an active part, he should be made to feel free to discuss the medical reasoning and the course of treatment of a case by his seniors and even encouraged to offer criticism, provided that in so doing he can clearly show that his opinions are founded on sound and accepted medical facts Training of this sort, besides acting as a stimulus to the attending staff, will provide the intern with the necessary incentive toward clear-thinking, and even more important, perhaps, toward a courageous expression of his opinion

With the foregoing ideas in mind it is evident, therefore, that the pathologist has

offered to him an excellent opportunity to pioneer in an unexplored territory, in so far as the non-teaching hospital is concerned In so doing he can be assured of the enthusiastic support of his medical staff At the same time he will not be long in realizing that his progress along these lines will have aided in correcting the impression that the clinician often has of the pathologist as being a myopic individual whose bounds of vision do not extend beyond the walls of the laboratory By such efforts he will have substituted instead, the picture of a consultant primarily and generally trained in the arts and science of medicine, but choosing to follow thereafter one of the more exact branches of the science

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M D , D R P H , *New York City*

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine

Prevention

Reading in the newspapers about the young woman who recently killed her girl friend and said, "I don't know why" and "For about a year I've frequently had an impulse to kill", recalls other cases where similar crimes *could have been prevented* The reports quote her as saying that she had wanted to be examined by a psychiatrist but that *nobody took her seriously*

A patient laboring under another form of mental disturbance, a manic, came to see me four years ago, complaining about his wife's infidelity He was sure that she had other men at his home when he was away And although he never saw it, he "knew" that she and they were "honeymooning and dearying all around the place until it sickened him" When I met his wife I was at once convinced that he was tortured by paranoid ideas of persecution For she was a poor, distorted cripple and the mere thought of her being sexually faithless was highly ridiculous Indeed, in accordance with all the laws of reasoning, she should have been the jealous partner, as her husband was physically sound and well-built. But a mental quirk, which could also be explained

in a rational way, made him the accuser Not only she denied the accusation and not only his own brothers concurred with her, but a study of her personality, a check-up of her time—she was a hard worker and housekeeper who never dressed up and never went out, all devoted to husband and children—confirmed her perfect, and perhaps enforced, honesty On the other hand this man was ill beyond a shadow of a doubt.

After a short time he improved and, to all intents and purposes, appeared normal But he as well as his family were warned about a recurrence and told that the patient must not discontinue to see the doctor and should be under psychotherapeutic care and observation for a long time.

A few months later there was another crisis One of the men who was supposed to be a rival, entirely unknown to our patient's wife, but a childhood friend of his, happened to die The patient was heart-broken. He cried bitterly Why had he estranged Bill? Why had he thrown mud upon his pure and innocent character? Why had he not spoken to him for years? How will he ever prove to him now that he had

really loved him? That it had all been a mistake? What will he do? No imploring will help. He could never show his regret, he could never obtain a pardon. To whom shall he talk? To the earth? To the open grave?

Unwillingly, Freiligrath's, last century's great German poet's verses came to mind "*Oh lieb', solang du lieben magst, Die Stunde kommt, die Stunde kommt, Wo du an Graebem stehst und klagst!*" Yes, the poet felt with this patient and with other unhappy individuals that when the friend was gone it was too late to love and that one could only pour out his grief and wail and mourn without result.

However, after some conversations he overcame that too and he was again asked to come at regular intervals. He promised and his family promised for him. But he failed to show up.

Three and a half years passed. Each time I saw his brothers I would caution them, but they would assure me that our man was in good mental health, that he was getting along "fine" with his wife and children "and everybody."

Then one day, a few months ago, a member of the family came to call me to the hospital where the patient was interned. I dislike seeing patients in stages of illness where I feel helpless and where staying in an institution is not only the sole therapy possible, but where the mere being away from the familiar people and objects may sometimes really effect a cure or a restoration to routine life. I also find it utterly useless to mix into the work or treatment of any hospital. In spite of that I decided to yield and visit this patient where he was. I changed my day's program and was ready to go when a telephone call informed me that it was too late: the patient was dead, a suicide, in his hospital room.

What had happened?

A few days previously our client went, after a day's hard work, to a banquet and ball of his benevolent society where he spent the night amid great excitement, overeating,

drinking excessively and dancing much. I had, of course, forbidden long before and repeatedly such conduct or anything likely to be a contributory cause to a bad attack, but I cannot tell how many times I had been disobeyed. He came home at seven o'clock in the morning, could not sleep, and had his fit.

He tried to cut his throat with a knife. When his wife interfered, he bit her and threw chairs and dishes at her and would have killed her had not the neighbors rushed in. Then he was taken to the hospital.

Had he been completely well during the three and a half years in which I had not seem him, as I had been assured? Not at all, as further questioning of the family proved now, after his death. It appeared that he used to bring home stories about all sorts of suspicions concerning his fellow workers in the shop and had many persecutory ideas. Once or twice, it seems, he was taken to his lodge doctor who found that there was "nothing the matter." At least so I was told by my informants.

It is impossible to be absolutely certain about it, but in the light of other cases of the same kind there is great probability that, with more cooperation, this tragedy could have been prevented at a time when the patient's mental condition was less advanced.

Let me take this opportunity to say that after very many laudatory letters of medical readers—some from specialists—urging me on to write because of the usefulness of these case reports to the general practitioner, I just received a discouraging note from one of the doctors. He said that while "he knew nothing at all about mental hygiene or psychotherapy he did not see how prevention of insanity was possible." I answered by comparing this work with the advisability of taking measures to prevent pulmonary tuberculosis in certain cases of subacute or subchronic bronchitis. But this story from life is a better reply. I have no doubt that all psychiatrists will agree with me.

NEW TREATMENT FOR DEMENTIA PRECOX

Dr. Manfred Sakel of Vienna, the originator of the Hypoglycemic Treatment for dementia precox, is visiting the United States and at present is at the Murray Hill Hotel in New York City.

Upon the invitation of Dr. Frederick W. Parsons, Commissioner of the Department of Mental Hygiene in New York State, Dr.

Sakel is holding a clinic at the Harlem Valley State Hospital, Wingdale, to teach a group of selected physicians from the institutions in the Department the technic of this new form of therapy.

Dr. Parsons has authorized each State Hospital to send a physician to the Harlem Valley State Hospital for such instruction.

Things to Know

Some physicians are apparently unaware of the fact that, in the capacity of employers, they come within the provisions of the Social Security Act. Agricultural workers and household servants are exempt, but chauffeurs, secretaries, and office assistants (clerical and nursing) are not. Physicians who have failed to report employees falling in any of the included categories should immediately inquire of their local postmaster how to make good the omission.

The old age benefit provisions of the Social Security Act take effect with the New Year. The first levy is on January wages, and the employer must make the required payroll deduction every week, fortnight or month, according to the interval of payment. The employee's contribution, plus the employer's tax, must be forwarded monthly to the local collector of internal revenue. Regulations obtainable at the Post Office and local branches of the Internal Revenue Bureau describe the records employers must keep, the information required on returns and all other essential details.

The physician in private practice, as an "independent contractor," is not subject to the employee's tax (or eligible

for benefits). Those employed on a salary basis, whether part or full time, are however considered employees and must use Form SS-5 to apply for "account numbers." Their salaries are subject to deduction of the employee's tax and their employers must pay a corresponding sum in their behalf.

The aversions of physicians to the clerical routine of filling out forms is well-known and understandable. When such requirements are law, however, prompt and careful compliance makes it easier for the practitioner as well as the state.

Every Doctor's Business

The assembly of the State Legislature this year should give the signal for physicians throughout the state to rally for effective political action. In spite of the President's recent assurances to the medical profession in regard to its role in the formulation of national health policies, there are many indications that the advocates of obligatory prepayment for sickness are endeavoring to force their program through by means of organized propaganda designed to create the impression of a public demand for state controlled medicine.

Heretofore New York has been quick to follow Washington's lead in social reform. In view of the present ascendancy of professional welfare workers in the national capital, there would undoubtedly be a disposition to return the compliment. The enactment of a compulsory health insurance act in New York would greatly stimulate the movement for national legislation along the same lines. Before the country has time to grasp their significance, a beginning trickle of such laws is apt to become a flood, sweeping before it the high standards of private medical practice and the incentives, opportunities, and initiative of the private practitioner.

It is part of the American temperament to legislate in haste and repent at leisure. National Prohibition furnished a notorious example of this trait. The present Social Security Act and tax on undivided profits are equally pertinent cases in point. Both these laws were passed without sufficient study—legislative sacrifices on the altar of political good intentions. Both will require extensive revision to make them compatible with fairness and good sense. Meantime their vicious features are the law of the land.

This is contrary to the scientific method which investigates thoroughly and applies new theories only after they have given convincing proof of their safety and effectiveness. Perhaps that is one reason why medicine has gone so far ahead in the past fifty years while politics has, to be charitable, stood still.

Physicians were not greatly interested in politics as long as politicians steered clear of medicine. Today, however, when every legislative session holds a potential threat to the independence and integrity of medical practice, it is the practitioner's duty to keep informed of legislative activities and muster all the political influence at his command to defend the security of his profession and the public health.

Extension of Diphtheria Immunization

The public and the medical profession as well have reached the stage where they view the decrease in the number of diphtheria cases as a matter of course. The intense activity which had been required to bring this about is often overlooked. That we must still be as vigilant as ever is brought home to us in a report of Anderson, Goldsworthy, and Ward.¹

They studied 184 cases of a severe form of diphtheria caused by the *Corynebacterium diphtheriae*. This grave form of the organism produces a malignant variety of the disease which does not yield to antitoxin. It is believed that the grave type either produces more toxin or forms it more rapidly so that a lethal dose is absorbed before antitoxin is injected. In one instance in their series of cases, death occurred despite the intravenous administration of 100,000 units within twenty-four hours after the onset of the symptoms.

They know of no case where a Schick-negative patient died from diphtheria. This is a strong and convincing reason for continued efforts in prophylactic immunization. We must not place all our faith in antitoxin alone, since diphtheria can assume a form which will not respond to it. It is with immunization that our chance of conquering the malignant type of this disease rests.

Pneumonia Control

Elsewhere in this issue [p. 80] is a reprint of the pamphlet issued earlier in the year by the State Department of Health entitled "Medical Care of Pneumonia." In it are to be found all modern methods used in the treatment of pneumonias. With the time of the year rapidly approaching when the acute upper respiratory diseases will reach their peak,

¹ Anderson, P. M. Goldsworthy, N. E. and Ward, H. K. *Med J of Australia* 2 350, 1936

the Health Department, with the cooperation of our State Society, is placing all available knowledge on this subject before the profession

While the pneumonia problem still awaits solution, our understanding of the question has been furthered. If we are to reduce materially the mortality attendant upon this disease, we must familiarize ourselves concerning all the recent advances in the prevention and treatment of the pneumonias. The problems of prophylaxis, oxygen therapy, serum therapy, should be thoroughly mastered and the indications for the various modes of treatment understood.

In its Pneumonia Control Program, the Health Department of our state not only places its available data at the disposal of the profession but in addition offers its facilities for the serum treatment of Type I pneumonia.

CURRENT COMMENT

"AMERICA DOESN'T GIVE A DAMN" is the title of an article by the caustic Mr. Channing Pollock in the November issue of the *American Mercury* from which we quote at some length. "A people capable of righteous wrath or even capable of unrighteous wrath—may save themselves on the brink of the precipice. But every people satisfied with bread and circuses have fallen into the hands of a Caligula, a Mussolini, a Hitler, or a Stalin. Apathy is the most unmistakable symptoms of physical, mental, and national breakdown. Men die of hardening of the arteries, nations of softening of the spine. The process is always the same—a simple, vigorous race fighting for existence, acquiring luxury, becoming enervated and decadent, learning to live without labor, bartering its liberties for governmental largesse, and finally passing from the hands of domestic tyrants into those of foreign tyrants. This is the history of Rome, of Athens, of Carthage, of Persia, of Spain, the age-old record forever being played on new phonographs ***"

Speaking of politicians, the author claims that "For nearly four thousand years, politicians have remained the lowest form of animal life."

In conclusion he states that "Few democracies have survived more than two hundred

years and this is not a propitious time for democracy." A democracy militant and alert and simple may survive—"but not a democracy more interested in golf than in government, in lotteries than in learning *** America can slide easily into Communism, Fascism, or a combination of both. If it doesn't, soon or late it must face a Fascist world in an armed conflict for which it is mentally, physically, and morally unprepared, in which it won't last as long as the proverbial dog with tallow legs chasing an asbestos cat through hell ***"

"Are we going down, like the *Titanic*, with bands playing and passengers dancing, or are we ready to clear our minds and roll up our shirt sleeves, 'that government of the people, by the people, for the people shall not perish from the earth'?"

"*** OUR CONTENTION *** is that, above and beyond its present progressive efforts to improve the quality and availability of medical care, the organized profession will shortly face the greatest struggle in its history to preserve the economic foundations of its triumphant art and science against a proposal that is at once one of the most idealistic and one of the most tragically impractical 'social welfare' projects ever conceived,—compulsory health insurance.

"One of the most hopeful auguries for eventual success in the coming struggle is the fact *** that when a reasonable, intelligent, unprejudiced person examines both sides of the case for compulsory health insurance, he almost invariably emerges from his study to oppose the proposal. The more light is shed upon it, the more evident its monstrosity becomes *** If Public Opinion eventually 'jells' in favor of compulsory health insurance, it will do so only because the physicians have failed to do their duty,—duty to the public welfare as well as to their profession,—in bringing out the *real issues*."—From an editorial in the December issue of the *Westchester Medical Bulletin*

"SCIENCE COULD STOP TODAY and not do another thing for a hundred years, and government could not catch up with it."—An opinion voiced by Mayor LaGuardia of New York City

"LIKE THE ENDURING PROBLEMS OF PHILOSOPHY which have no permanent solution, but are of necessity posed afresh for each generation in terms of its own deeper and

more inclusive insights, the persistent problems of human relations can be solved only by adjustments which are valid for limited periods of time and for particular cultural conditions. This fact does not, however, render their solution less imperative. Such continuing adjustments are essential to any coherent evolution of society and this is especially true in the field of international relations, upon which rest ultimately the issues of war and peace * * *

"An unbridled and truculent nationalism, such as we have lately seen running amuck in various parts of the world, selfishly claiming everything for itself, spotless virtue along with the rest, conceding neither moral decency nor economic honesty to any other nation—such paranoic nationalism, of which we have had more than a few faint echoes on this side of the water, if allowed its head, will ultimately reduce civilization to a mere shambles, from which nothing but obscene horror can emerge. Yet collective security is something of which officially we will hear nothing, an objective toward which we will contribute nothing, save weak and grudging lip service, and not much of that beyond a few innocuous platitudes. Nominally we desire peace, but we are not willing to pay much for it except in terms of battleships and army corps, which have by the way, no more than our favorite doctrine of isolationist nationalism, prevented our participating in five wars in our century and a half of national existence, and in two cases at least with utterly demoralizing consequences for our subsequent economic life * * *

"Being an incorrigible optimist, I have no personal doubt that we shall discover ways in which we may do full justice to the social and economic necessities of our people without wholly crushing that individual initiative and self-reliance upon which our achievement as a nation has been so largely

founded. But the solution of the problem will require the best intelligence we can command, with the honest co-operation of every class and group, and above all, patience and good will"—The above are excerpts from a speech by James Rowland Angell, President of Yale University, made at the Annual Banquet of the Chamber of Commerce of the State of New York.

"FOR LABOR TO CONSENT to socialized medicine of the European type is for labor to acquiesce to socialization of itself * * *"—One of the "Timely Brevities" to be found in the supplement to the *Bulletin* of the Broome County Medical Society of November 1936

"* * * ANY SCHEME WHICH UNWITTINGLY ENCOURAGES the prolongation of disability by the trouble-making psychopaths and maligners of every kind, or which results in the useless, inefficient and perfunctory professional services of physicians will be a social hazard and not a social benefit.

"If the health insurance plans proposed are prepared as hurriedly and as carelessly as in the case of the social security act, the inevitable excessive costs and disappointments due to failure to avoid obvious pitfalls will add further impetus to the rise in costs of living

"Also, ill-advised and hastily prepared legislation of this sort will add just one more factor encouraging the improvident and ignorant part of the community in its notion that they are entitled to living, with all the trimmings, without any obligations on their own part * * *"—George Hyslop, M.D. wrote the above to the *New York Herald Tribune* under date of December 8, and we believe it well worth quoting

INTERESTING INNOVATION BY QUEENS COUNTY

An interesting innovation by the Medical Society of the County of Queens is the publication in local newspapers of the names and addresses of members in good standing. The Queens Society asked the Executive Committee of the State body if this action would "be considered proper and in keeping with the Principles of Professional Conduct," to which Dr. Peter Irving, State Secretary, replied that the Executive Committee "considered thoroughly" the suggestion, and "considers such publi-

cation entirely in keeping with the Principles of Professional Conduct, and in no way violative thereof." President Dobbins of the Queens Society, remarks "This action by our Society is undoubtedly the most sweeping and progressive method undertaken by any similar Society in an endeavor to eradicate the charlatans, quacks and montebanks who flourish because of the sacro-sanct attitude assumed by a too conservative medical profession"

The Left Speaks Out

694 Miller Avenue
Brooklyn

To the Editor

Why does the editor of "Across the Desk" bring forth that decrepit and hoary tale of the W P A worker with the osteochondralgia to prove the iniquity of socialized medicine? Must we resort to such puerility to prove our cause? It seems to me that there is dignified evidence enough against socialized medicine without resorting to parlor car nonsense It is our inability to understand the basic problems of the underprivileged which will mitigate against us in our efforts against socialized medicine Perhaps the editor can offer suggestions as to how we can eliminate the 10,000,000 unemployed without resorting to the lethal gas chamber Somebody in Washington who ought to know something about our economic

set up admits sadly that like the poor, the 10,000,000 will always be with us Has the editor any available jobs for the W P A workers? I am sure that they would gladly snap at jobs that would again dignify them as productive human beings with money for food, shelter and a private doctor Why not jokes about a system that allows such a colossal waste of human resources?

The editor would further lead us to believe that nothing rational or intelligent can emanate from the left Thus by inference we are to look to the right for wisdom, honesty, stability, and lower taxes And to prove his contention the editor shows that by the government aiding the poor Southerners with jobs and food, pellagra is on the decline Consistency thou art a jewel

GEORGE S MEISTER, M D

December 6, 1936

VALUE OF THE COUNTY SOCIETY

An editorial tribute to the value of the County Medical Society appears in the Mt. Vernon, N Y, *Argus* It notes that at the annual meeting of the Medical Society of the County of Westchester, which was the 139th such meeting, thereby marking the association one of the oldest in the country, it was announced that membership had increased in 4 years from 482 to 638

That increase, it goes on to say, does not so much indicate a greater number of physicians in the county or any greater necessity for medical care as it indicates the strength of the medical society and the gradual enlargement of scope because of public service

The general public may not be aware that the medical society has grown in its responsibilities to a far greater degree than in its membership To recount a few of the listed forty-four accomplishments reveals the widespread functions

A published bulletin on technical matters, contacts with health, welfare and social agencies, a public information service for

press reference, special news releases of an educational nature, local advisory committees in welfare service, a survey of "specialty services" in hospitals, legislative activities, research, cooperation with parent-teacher associations in pre-school examinations, participation in administration of emergency relief through federal agencies, supplying speakers to lay groups,

Also, cooperation with authorities in prosecution of illegal practitioners, cooperation with clinics, establishment of standards of obstetrical service, standards, also, in professional control of anaesthesia, cooperation in workmen's compensation cases, a collection service to members, legislation in supervision of the sale of proprietary preparations, opportunities for post-graduate training to members

These activities, it will be noted, are principally of two kinds, to the public and to the society's members The latter also serve the public through improvement of the standards and practices of the members themselves

PROCEEDINGS OF THE COUNCIL

Particular attention was accorded by the Council to certain matters of present interest at its meeting on December 10, 1936

Conference with State Hospital Association

The Committee appointed to enter into conferences with the State Hospital Association, reported a successful first conference as follows

"On December 3, 1936 your special committee entered its first conference with a similar committee from the State Hospital Association, and is happy to report that it believes that an entente cordiale has been established which should enable the two organizations to discuss any subject of common interest, even if controversial, in full amity and, therefore, to greatest effectiveness

"It was clearly brought forth in this first conference that both hospitals and physicians have equal need of each other in their combined effort to supply good medical service to the community—not only now, but in any future sociological set-up

"Discussion was held on a number of subjects, some of which led to immediate preliminary accord in principle, and some of which were set aside as open questions. In particular, it was decided that where legislation affecting both hospitals and the profession may be under consideration both organizations should seek conference before a definite legislative stand be taken"

Limitation of Anesthesia to Physicians Only

The House of Delegates, in April 1936, issued a mandate to the Committee on Legislation to secure passage of a bill by the 1937 Legislature, which would restrict the giving of anesthesia to physician anesthetists, but since that time a mass of information has come to hand, which has led the Council to record a contrary instruction for this year, at least. Under the By-Laws of the State Society this action of the Council can only become effective or binding on the Society if approved by a majority of a referendum vote of the House of Delegates, "provided a majority of the House of Delegates vote thereon within fifteen days after the mailing of the question submitted for referendum." The members of the 1936 House of Delegates will receive in due course,

from the Secretary, the question for referendum vote

With the question will be submitted a memorandum, detailing the reasons for this change of front.

Briefly, the New York members of the American Society of Anesthetists and the American Society of Regional Anesthesia presented, through Dr T Drysdale Buchanan and Dr Paul Wood, a suggestion that no bill of the kind be supported this year, if not longer. Their reasons were *first*, that there are at present too few physicians as anesthetists to replace the seven hundred or more nurse anesthetists now giving anesthesia throughout the State, *second*, that many hospitals would be obliged to make difficult, rapid readjustments in service, *third*, that there are many surgeons in the State who are not as yet persuaded of the wisdom of limitation. Delay would give time for all those interested in eventually limiting the administration of anesthesia to physicians, to do some missionary work through the State. The eventual result of such activity it was thought by these gentlemen, would be acceptable legislation at a later date

The Committee on Legislation of the State Society has accumulated information from many sources that appears to prove that such a course of action by the State Society wise

Physicians' Duties Under the Education Law

On recommendation of the Committee on Public Health and Medical Education, the Council will suggest to the State Department of Education that it prepare and issue a pamphlet to all new licentiates—the pamphlet to contain the essential information in regard to technicalities in the Education Law, to be observed by all physicians, particularly in the matters of local registration and annual registration

Physicians' Duties Under the Public Health Law

The Council decided to suggest to the State Department of Health that a revised pamphlet be prepared and issued to all new licentiates—this pamphlet to contain information essential for every physician to know in regard to the Public Health Law and as to the Sanitary Code of New York City

Statement of Proposition No 3 of the Booth Report

This part of the Booth Report, which was adopted by the House of Delegates in April 1933, reads as follows

Proposition No 3

There is in every community a group of people below the "comfort level," on whom the costs of medical care impose a heavy burden. These are self-respecting people of the salaried class in most instances, whose living expenses are met from their weekly earnings. For them the greater part of medical costs comprise charges for hospital and nursing care.

To lessen the burden of hospital and nursing care for this wage-earning group, your Committee recommends the adoption generally of a plan of hospital insurance, whose principles may be stated as follows:

(a) Members of employed groups may receive for the payment of a small annual sum hospital care in semi-private accommodations for a period of 21 days in any one year, such care to include bed and board, general nursing service, x-ray and laboratory examinations.

(b) All reputable voluntary hospitals and some proprietary hospitals be entitled to participate in this plan.

(c) Except in emergencies, all admissions of patients cared for under this plan must be made through the patient's personal physician.

(d) Certificates of membership issued to subscribers shall state specifically that the service does not cover the fee of the patient's physician.

(e) In each community under the supervision of its organized medical group there shall be developed the details of this plan so as to meet local conditions and make it workable.

On recommendation of the Committee on Economics a re-statement was adopted which would rescind sub-sections (a), (b), (c),

(d), (e) of Proposition No 3 above and substitute the following:

(a) Hospital care shall mean provision of bed, board, general nurse service, customary surgical dressings and medicines, and other facilities of the institution not including medical care, as defined in (b).

(b) Medical care shall mean any procedure or service by a licensed physician acting under authority of Section 1250 of Article 48 of the Education Law of the State of New York.

(c) Hospitals making contracts with organizations, acting under Chapter 595 of the laws of 1934—the Insurance Law of the State of New York—shall not implicate themselves with conditions inconsistent with the principles and definitions herewith stated.

(d) The operation of such hospital insurance in any community shall not discriminate against any reputable institution, whether voluntary or proprietary.

(e) Admission of patients for care under the benefits of such hospital insurance shall be only through reference by a private physician. Exemption to this provision shall be made for the exigency of any emergent need.

(f) Certificates of membership in such association shall specifically state that the insurance does not provide for any medical care as defined in (b). Actual wording of the certificate to be approved by the local County Medical Society or Societies.

(g) Every hospital insurance plan operating under the aegis of this Proposition shall develop the details of its operation to conform with such principles and policies as from time to time may be determined by the local County Medical Society or Societies.

(h) When it is so desired by the local County Medical Society satisfactory representation from the membership of the local County Medical Society on the Board of Management of the hospital insurance shall be arranged.

Income Tax Deductions for Charitable Service of Physicians

A suggestion from a member of the State Society that some effort be made to secure to physicians the right to make deductions for charitable work, such as is performed in hospitals and dispensaries, was considered. The Committee on Economics held the suggestion impractical of accomplishment to a full measure of relief, and the Council decided to take no action.

Practice of Psychology

The Association of Consulting Psychologists, Inc., approached the State Society in the effort to get its backing for a law which would define the practice of psychology and set up a mechanism for certification of those adjudged fit to practice under a new law. The Law as proposed defined the practice of psychology in the following words:

"The practice of psychology" is defined within the meaning and intent of this article as the application of the principles and technics of the science of psychology to the measurement, evaluation, explanation, interpretation, motivation, guidance, education (or) re-education of human behavior.

The Public Relations Committee met with eminent members of the teaching staffs of several universities, with the Commissioner of Mental Hygiene of the State of New York, with Dr Israel Strauss of the Board of Psychiatric Examiners and Dr Lloyd H Ziegler of Albany. It was considered by this Committee that the Law as proposed could not fail to invade in some measure the practice of medicine as defined by the Medical Practice Act. It, therefore, recommended that backing be not

given to this proposed legislation in its present form, and the Council adopted this recommendation

Syphilis Control

A request from Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, that a committee be appointed to advise with him and with the Commissioner of Health in New York State led to authorization of the President to designate such a Committee. It was Dr. Parran's hope to have suggestions from such a Committee after review of the available information on the syphilis problem in this State, with any recommendations that seem desirable.

Dr. Parran enumerated the following questions for solution in syphilis control

1 The system of notification most suitable to physicians, patients, and health agencies

2 The additional laboratory facilities needed for diagnosis of syphilis

3 The policy recommended in the distribution of antisyphilitic drugs

4 The adequacy of free treatment facilities for those who cannot pay physician's fees

5 The nature and extent of the additional facilities needed

6 The physician's part in the application of epidemiologic methods for the control of syphilis

7 The possibility of developing minimum standards of treatment for early syphilis

8 The availability of hospital beds for treatment of cases needing hospitalization.

9 Methods for the more adequate prevention of congenital syphilis through recognizing and treating the disease among pregnant women.

10 The lines along which informative and educational programs should be conducted.

11 The possibilities of prophylactic measures being taught and administered through physicians' offices, outpatient hospital services and clinics, with the thoroughness and precautions governing Army and Navy procedures

The President designated the Committee on Public Health and Medical Education to represent the State Society in this matter

PETER IRVING
Secretary

BEAUTY AIDS THAT "KNOCK YOUR EYE OUT"

We hear sometimes of beauty so stunning that it "knocks your eye out." Now it seems that some of the beauty preparations do the same thing. Indiscriminate use of weight reducers, hair dyes and depilatories is causing serious injury to eyesight in the United States, according to a warning by Dr. Walter I. Lillie, in the current issue of *The Sight-Saving Review*, quarterly journal of the National Society for Prevention of Blindness.

Case stories of eye tragedies among his patients are cited by Dr. Lillie, and he gives the trade names of the "beauty products" which the victims used. Dr. Lillie is a practicing ophthalmologist in Philadelphia, and a member of the Department of Ophthalmology of the Temple University School of Medicine there. Writing on "Cosmetics Detrimental to Vision," he says:

Individuals who use cosmetics are unwittingly subjecting themselves to visual dangers. We are all potential victims, because the present antiquated Food and Drug Act, passed in 1906, only requires the manufacturers of food and drugs to properly label their products but does not penalize the acts of adulteration and misbranding. False and fraudulent therapeutic claims must be proven before the product can be removed from the market.

These two little words "and fraudulent" compel the Government to prove that the manufacturer knows the customer is being swindled.

This has prevented any adequate control over quack or dangerous remedies. Extraneous advertising of these products through the news papers, magazines and radio is without Federal control, and because of this we are constantly reminded of the wonderful benefits and cures that will be derived from their use.

Today the billion-dollar-a-year cosmetic industry is not subject to any Federal regulations unless the labels bear medicinal claims, which, of course, never occurs. There is no legal way to protect the public against dangerous cosmetics. Toilet preparations which are known to be harmful by the medical profession cannot be taken off the market regardless of any disfigurement or injury they may inflict. Although poisonous cosmetics that ravage their users by paralyzing, blinding or disfiguring them are the exception rather than the rule, the medical profession should be alert to the possibilities and probabilities of visual and bodily damage which may result from their use.

The untoward visual effects may be temporary or permanent, depending upon the nature of the ingredient or the amount used, and the tolerance of the individual. The eyes are usually affected in one of two ways, either through direct contact with the preparation or indirectly through the absorption of the poisonous ingredient in the body. Three groups of cosmetics have the potentiality of producing severe ocular damage, namely (1) weight reducing preparations, (2) hair dyes, and (3) depilatory ointments.

WORKMEN'S COMPENSATION

Revised Rules and Regulations Promulgated by the Industrial Commissioner covering Chapters 258 and 930 of the Workmen's Compensation Law

1 Medical Compensation Boards must pass upon the application of a physician within sixty days and notify the Industrial Commissioner of its action. If such Board fails to recommend that a physician be authorized to render medical care under Chapter 258 the physician may appeal to the Industrial Council, as provided in clause (G) of sub-division four of section ten-a of the Labor Law, who thereafter has sole jurisdiction.

2 Removal of physicians from panels and revocation of licenses of medical bureau, Section 13-d.

The recommending compensation boards shall investigate, hear, and determine all charges of professional, or other misconduct by any authorized physician or by any licensed compensation medical bureau under rules and procedure prescribed by the Industrial Council as follows:

(a) The physician or Medical Bureau accused of misconduct shall be given twenty days notice of the charges in writing including a bill of particulars setting forth the specific section and subdivision of the law violated and the time, date, and place of the hearing.

(b) Careful records shall be kept of the minutes of the hearing.

(c) These records, together with the report of the Board of the Medical Society or other Board, with its findings shall be submitted to the Commissioner.

Appeals filed by physicians and medical bureaus with the Industrial Council shall be referred to the sub-committee designated by the Industrial Council to ascertain the facts and report its findings to the council for final action.

(a) The physician or medical bureau may file an appeal with the Industrial Council from the decision of the Medical Society or other Board.

(b) The physician or medical bureau appealing and the Medical Society or other Board whose decision was appealed from, shall be notified in writing indicating the time, date, and place of hearing.

(c) The physician or medical bureau may be represented by counsel.

(d) Accurate stenographic or stenotype minutes of the hearing shall be kept for the files of the commissioner and Industrial Council.

3 When a physician in association or in co-partnership with another physician or physicians, or through another physician or physicians as employees or agents, main-

tains and operates one or more offices principally for the treatment of injured claimants under the Workmen's Compensation Act, he shall secure a compensation medical Bureau license.

4 All reports, except form C-104 filed by attending physicians and specialists must be verified before a Notary Public or a Commissioner of Deeds, to insure their value as prima facie evidence in a compensation case.

5 All specialists, consultants, etc. shall submit a report of their findings in triplicate, one copy to the Industrial Commissioner, one to the attending physician, and one copy to the employer or insurance carrier. If the specialist acts as attending physician, he shall file a forty-eight hour report with the employer or carrier and with the Industrial Commissioner.

6 All medical reports filed by attending physicians and specialists must contain the the authorization certificate number and code letters.

7 When it is necessary for the attending physician to engage the services of a specialist, consultant or a surgeon, or to provide for physiotherapeutic procedures costing more than twenty-five dollars or to provide for x-ray examinations and special diagnostic laboratory tests costing more than ten dollars, he must secure authorization from the employer or insurance carrier or the Industrial Commissioner. Such authorization is not necessary when special services are required in an emergency or when authorization has been unreasonably withheld. Section 13-A-5.

8 The authority of an employer for the services of a specialist, in excess of a \$250 fee, applies only to the necessity for such services, but the choice of such specialist is entirely within the jurisdiction of the injured worker.

9 When it is in the interest of the injured employee, and where an x-ray is required and it is impossible to secure the services of a qualified x-ray specialist, the Board of the local County Medical Society may designate a specially qualified individual to take x-ray pictures under the supervision of the attending physician. The attending physician, however, shall render a bill for such service to the employer. This in no

way, however, deprives the employer or insurance carrier from having other x-ray pictures taken if they so desire

10 A physician authorized to treat workmen's compensation cases, when requested to supersede another physician, must, before beginning treatment of such patient make reasonable effort to communicate with the attending physician to ascertain the patient's condition. The superseding physician must also advise the attending physician of the name of the person who has requested him to assume care of the case and state the reason therefor. If the second physician cannot contact the attending physician, and the claimant's condition requires immediate treatment, the said physician should advise the doctor previously in attendance within forty-eight hours that he now has the patient in his care. The preceding physician shall supply the succeeding physician with a complete history of the case.

11 In the event of a serious accident requiring immediate emergency medical aid, an ambulance or any physician may be called to give first aid treatment.

12 A registered physiotherapist may treat workmen's compensation cases at his own office or bureau when the case is referred to him by an authorized physician. The authorized physician should, however, give written directions to the physiotherapist as to the kind of treatment to be rendered and the number of treatments to be given. These directions must be given in writing by the physician and shall constitute a part of the record of the case.

13 Bills for x-rays and consultations shall be submitted for payment directly to the employer or carrier by the specialist rendering the service. These services must be authorized in writing by the physician in attendance.

14 Physicians treating claimants in hospitals may secure the signature of claimant for authorization to obtain copies of any necessary hospital records.

15 The physician in attendance in public hospitals must be the judge as to when the

"emergency status" of the case has terminated. In case of a dispute the matter shall be referred to the Compensation Board of the Medical Society of the county in which the hospital is located, for immediate decision.

16 Medical inspectors of insurance companies shall be admitted to hospitals or other institutions where injured employees are confined, upon proper identification, for the purpose of complying with Section 13-J.

17 A hospital may not secure a license to operate a medical bureau to render care to compensation cases.

18 No license is necessary to operate a first aid station for emergency treatment but no subsequent treatments are to be rendered by any one other than a qualified physician.

19 No advertising matter of any nature, on compensation work, by authorized physicians, medical bureaus or laboratories shall be permitted.

20 No insurance company or self insurer may reduce the size of notice to employees (Form C-105) which is to be placed in all places of employment covered by the Act, unless such permission is granted on application to the Industrial Commissioner.

21 Section 13-f-2 applies only to the physician selected by the claimant to treat him as provided by Section 13-a. Such doctors are entitled to a fee for attendance at a hearing when subpoenaed by any party in interest or when directed to do so by a Referee or when produced by an insurance carrier or employer.

22 Hospitals shall render bills for board and room accommodations, medical and surgical supplies, nursing facilities and routine laboratory service. Bills for all services rendered by physicians in hospitals, including physiotherapy, x-ray, pathology, anesthesia, medical, and surgical care, etc shall be made out separately and paid directly to the doctor rendering the service. Proper reimbursement by the physician to the hospital for materials and the use of facilities will not be in violation of Section 13-D-2 (e).

Rules governing recommending of authorized physicians by insurance carriers and employers and the procedure to be followed by medical inspectors and consultants

23 The supplying of names of authorized physicians by insurance carriers to their policy holders is in contravention to Section 13, as amended by Chapter 258 of the laws of 1935. Such policy holders and all employers may secure a list of all authorized physicians in the vicinity of their places

of business by applying to the Industrial Commissioner of the Department of Labor.

24 Any physician who acts in the capacity of medical inspector for an insurance carrier or employer in the case of an injured employee under the care of another physician shall not participate in the

treatment of said injured employee except in the operation of a rehabilitation clinic or bureau under Section 13-j of the Law. Nothing herein contained affects the right of transfer as provided in Section 13-a (3)

25 When a medical examination is had under Section 13-a (4) it shall be by a qualified physician at a place reasonably convenient to the claimant and in the presence of the claimant's physician, if in the latter's opinion his presence is necessary. A duplicate copy of all notices of requests

for examinations must be sent to the attending physician

26 No physician designated by an insurance carrier or an employer as a consultant in the case of an injured employee, shall subsequently participate in the medical or surgical care of said injured employee, except with the written consent of the injured employee and his attending physician. Nothing herein contained affects the right of transfer as provided in Section 13-a(3)

Rules governing the licensing of and operation of compensation medical bureaus

27 The character and frequency of accidents, the number of employees in a given plant and the availability of qualified medical care in the immediate vicinity of the place of employment should be considered in relation to the authorization of an employer's compensation medical bureau

28 The bureau should be located in the industrial plant or in the immediate vicinity

29 The question of the necessity of the presence of a physician during working hours, or the availability of a physician at stated hours should be determined by an inspection of the plant to ascertain the nature of the hazards and the frequency of accidents

30 The bureau shall be well housed with sufficient space, light, and air and shall conform to reasonable sanitary requirements. Proper facilities in the form of personnel for assistance in emergencies, instruments, sterilizers, dressings, drugs, shall be available at all times and in amounts proportionate to the size of the plant and the number of employees. Such facilities shall be adequate for more than mere emergency care and for the more severe type of industrial injury

31 A bureau license may be given for a stated project which, because of the hazards of the project and the frequency of acci-

dents, requires continued medical care and such license shall be for the life of the given project only. In such cases all employees of all sub contractors shall be covered by the license.

32 No license shall be issued to an employer to cover any but his own employees except as indicated in Rule 31

33 First aid stations—No license is required to operate a first aid station by an employer of labor. Such first aid or emergency station should be properly equipped for first aid in accordance with the type of hazard encountered at the particular place of employment.

34 Form C-105, a notice of the rights of an injured employee and the responsibilities of the employer, shall be posted in each compensation medical bureau and first aid station

35 All compensation medical bureaus operated by summer camps and other institutions wherein such camps and institutions are operating for a profit shall be charged a license fee of \$25.00 per annum for the operation of such medical bureaus which are in operation for six months of the year or less

ELMER F. ANDREWS
Industrial Commissioner

December 1, 1936

TOKYO FOR STERILIZATION

A dispatch from Tokyo, says the Japanese Government plans to submit to the next meeting of Parliament a bill for sterilization of the insane, epileptics, confirmed alcoholics and persons of known criminal tendencies

Operations would be performed only after requests of persons affected, or of

insane asylums, penitentiaries and social relief institutions. After the requests a committee consisting of a judge, a government representative and two physicians would decide the question finally

The measure is similar to laws effective in Germany and some Scandinavian countries

PNEUMONIA CONTROL PROGRAM

Foreword

This pamphlet has been prepared under the joint auspices of the Committee on Public Health and Medical Education of the Medical Society of the State of New York, the New York State Department of Health, and the Advisory Committee on Pneumonia Control of the New York

State Department of Health composed of the following physicians Donald B Armstrong, Russell L Cecil, Rufus I Cole, Thomas P Farmer, Clayton W Greene, Peter Irving, George M Mackenzie, O W H Mitchell, George H Ramsey, Clarence L Scamman, Augustus B Wadsworth, and Arthur W Wright

Clinical Aspects of Pneumococcus Pneumonia

Definition

Lobar pneumonia is an acute infectious disease characterized by a massive inflammatory exudate into one or more lobes of the lung. The dominant clinical features are chill, fever, pain in the chest (or side) and cough, with the expectoration of viscid, rusty appearing sputum. In about 96 per cent of cases this form of the disease is caused by the pneumococcus. Consequently the term lobar pneumonia has come to be considered practically synonymous with the term pneumococcus pneumonia though the latter is actually more inclusive.

Bronchopneumonia or atypical pneumonia is also frequently caused by the pneumococcus, usually one of the so-called higher types, but may be due to streptococcus, influenza bacillus or other infection.

Since the bacteriology rather than the morbid anatomy of pneumonia is coming to be recognized as of the greater significance the present method of classification on an anatomical basis seems somewhat misleading and could advantageously be changed to emphasize the etiological agent.

Incidence and Distribution

In New York State pneumonia in its various forms causes a greater loss of life than any other communicable disease and is exceeded as a cause of death only by heart disease and cancer. While these two latter are diseases for the most part, of late life, pneumonia takes about 50 per cent of its toll during the ages of greatest useful-

ness. The annual loss of life from this cause in New York State is about 12,000.

Pneumonia is essentially a disease of winter and early spring. The four months from January through April include about 75 per cent of the cases in any normal year.

Etiology

The predisposing causes are recognized as being those conditions which tend to lower individual resistance or otherwise increase susceptibility and enable the causative microorganisms to gain a foothold. Specifically these are the common cold, grippé, influenza, measles, and whooping cough. In addition there are a number of less well established but probably, nevertheless, important factors such as extreme fatigue, malnutrition, chilling, and chronic alcoholism, which seem to contribute to lowered resistance.

The inciting cause is infection with virulent pneumococci or other microorganisms, presumably occurring during a period of susceptibility.

Among pneumococcus pneumonia reported in the past Type I has been responsible for about 33 per cent of all cases, Type II for about 23 per cent, Type III about 9 per cent, and Types IV to XXXII for the remainder. Type I pneumonia is particularly prevalent during early adult life but gradually yields to Type III as the most common single type in later years.

Epidemiology

Not a great deal is known about the epidemiology of this disease but recent studies and clinical observations support the

Reprinted from Circular 20 issued by the Bureau of Pneumonia Control, Division of Communicable Diseases, 1936

belief that pneumonia is a definitely communicable disease. This is felt to be particularly true of infections caused by pneumococcus Type I or Type II.

It is somewhat problematical whether or not isolation can be instituted, practically, before much of the damage has been done. Reasonable precautions, however, should be observed especially with respect to the care of respiratory secretions.

Studies of the occurrence of pneumococci carried in the mouths and throats of normal persons have been made with considerable care. These studies have shown that pneumococci of the higher types are frequently present while Types I and II are rarely encountered except in cases of actual pneumonia or its complications.

Diagnosis

Clinical. Early diagnosis is essential for adequate treatment. The diagnosis of pneumonia usually can be made upon the history and symptomatology without dependence upon evidence of consolidation or other physical signs in the chest.

The significant symptoms are a chill, sudden elevation of temperature, pain in the chest (or side), and a blood-tinged or rusty sputum. The occurrence of any of these singly or in combination, even though in varying intensity, must seriously raise the question of pneumonia. A preceding cold or attack of gripe is highly suggestive. The presumptive diagnosis so made may be positively established if prompt bacteriological studies show a Type I or Type II pneumococcus, the finding of other microorganisms being suggestive but not equally pathognomonic.

Physical signs in the early stages of pneumonia may be entirely absent. When they do appear the first signs are generally slight dullness to percussion, diminished breath sounds and possibly a few moist râles over the affected lobe. Eventually, but often not until the second or third day, the classical signs of consolidation may be expected to appear over the whole or part of the lobe involved.

Bacteriological. Thirty-two specific types of pneumococci have been identified up to the present time. These thirty-two types include practically but not quite all pneumococci known to exist. The important types of pneumococci, if present, can

usually be identified in about one-half hour from the time the sputum specimen is received at the laboratory by the use of the Neufeld method of typing. This method, which is done directly on the sputum specimen, offers a sharp contrast to the time-consuming methods formerly employed.

Strict attention should be given to the method of collecting the specimen, care being observed to obtain sputum raised from the bronchial passages rather than saliva or nasopharyngeal secretion. The specimen should be collected in a clean, or preferably sterile, container (a supply of which may be obtained from the nearest approved laboratory and kept on hand) free from antiseptics, preservatives or any other contaminating material and sent to the nearest laboratory approved for sputum typing without delay. Severe pleurisy may cause the patient to be unwilling to make the effort necessary to raise a satisfactory specimen. Under such circumstances, the application of local heat to the chest, a firm binder of strapping and an appropriate anodyne will often make better cooperation possible. Valuable time may be saved, especially at night or on holidays, by telephoning the laboratory so that it may be prepared to make the examination immediately upon receipt of the specimen.

In the absence of a satisfactory sputum specimen, as is often the case with children, an accurate typing can sometimes be obtained from mucus swabbed from the back of the throat during the act of coughing. Occasionally such a specimen will prove adequate for rapid typing, but cultural methods are likely to be required. The consequent loss of time together with the uncertainty of this method makes serious effort to obtain an actual sputum highly desirable.

A blood culture will occasionally prove the first or only means of making a bacteriological diagnosis.

Lung puncture, a technique of experimental value, is not generally applicable in private practice.

Roentgenological. X-ray offers an invaluable aid in doubtful cases and in the diagnosis of complications but should seldom be necessary in making the initial diagnosis.

Differential Diagnosis. Most difficult of distinction, if one is on the alert for an early diagnosis on the basis of symptoms, is severe gripe or influenza. Tubercu-

losis, especially in pneumonic form, can often be picked up by a careful history and sputum examination, but one may have to depend upon clinical observation over a period of time. Pulmonary infarct, pleurisy (from other causes), abscess, atelectasis, coronary thrombosis, may all simulate pneumonia in a number of respects, but each has characteristics that should distinguish it. Acute appendicitis and occasionally other acute abdominal conditions may lead to considerable difficulty in diagnosis. The leukocyte count may be of some value when the diagnosis is difficult, an excessively high count being considered suggestive of pneumonia.

Treatment

General Care The fundamental purpose of general treatment should be to obtain the maximum of rest compatible with adequate nutrition and elimination.

Symptomatic treatment may be required notably for the relief of pain, restlessness, excessive cough, tympanites, anoxemia, delirium, urinary retention, and excessive diaphoresis during the acute stage of the disease.

Relief of pleuritic pain is of great importance since the rapid and shallow respirations and severe suffering will quickly exhaust the strength of even the most robust patient. Often a tight chest binder or strapping, and codeine will serve to bring relief. Morphine may be used safely in the early stages, but too much morphine is undesirable on the ground that a totally abolished cough reflex favors bronchogenic spread of the infection by retained moisture and secretions. The barbiturates are usually effective in combating restlessness even in the presence of a moderate degree of delirium. If the sputum is excessively tenacious an expectorant may save the patient much loss of strength through hard coughing.

During the acute febrile period the patient should be maintained on a liquid diet avoiding such foods as are recognized as being gas forming or constipating. In the absence of cardiorenal complications the total daily fluid intake, in an adult, should be over rather than under three liters.

Abdominal distention often may be mimicked by the use of a small saline enema daily and a proper diet. Certain authorities

have recently stated that sodium chloride is of value in preventing tympanites. It is also claimed that excessive diaphoresis may be prevented by the same means. The usual amount given daily is five to ten grams, in capsules.

If distention appears it must be relieved promptly since increased intra-abdominal pressure may embarrass both the respirations and circulation. The use of routine measures such as a soft rectal tube, turpentine stupes, hypodermic injection of pituitrin (surgical) or physostigmine usually are sufficient. In some persistent cases a high colonic irrigation will prove effective. Occasionally, however, a case is encountered which fails to respond to these or even more drastic measures. In such instances the distention may be gastric or upper intestinal and marked relief sometimes may be obtained by the introduction of a nasal (Levine) stomach tube well into the stomach or duodenum. The tube may be left in place if necessary and conveniently used for giving nourishment and fluids, particularly in a comatose or otherwise uncooperative patient.

Anoxemia, cyanosis, and early delirium may be markedly relieved by adequate oxygen administration. Where an oxygen tent or chamber is available this presents the ideal method of administration. Recently an open top oxygen box has been devised which is both efficient therapeutically and economical to own and operate. When such facilities are not at hand fairly satisfactory results may be obtained by supplying the oxygen through a nasal catheter or tube. Funnels and masks as methods of oxygen administration have not proved satisfactory. The optimum oxygen content is generally considered to be between 40 per cent and 60 per cent by volume. Despite all assertions of various agencies to the contrary the only way that a safe oxygen content can be maintained in a tent or chamber is by regularly spaced analysis and appropriate regulation of the oxygen flow. Such analysis requires very little equipment and may be easily performed by an intelligent attendant. Once started oxygen therapy should be continued with only the minimum interruptions essential to nursing care until after the crisis or lysis has occurred.

Evidence of cardiac embarrassment or failure should be treated in the appropriate

manner The routine use of digitalis, however, has not proved of value Most authorities now recommend its use only in the presence of some pre-existing cardiac incompetence, sudden irregularity or other evidence of impending failure

For general circulatory failure the usual procedures should be followed Too much should not be expected of any form of treatment at this stage however The use of epinephrine, caffeine, and intravenous glucose are perhaps of most value, but seldom can more than a few hours delay of death be thus attained

The chronic alcoholic will certainly require an appropriate sedative such as paraldehyde, and a certain amount of whiskey at regular intervals Alcohol is not recommended in treatment by most authorities in this country, excepting under these circumstances

Specific Treatment * The effectiveness of Type I antipneumococcus serum has been established definitely When given early and in adequate amounts this serum has been shown to reduce the mortality from Type I pneumonia by 50 per cent to 66 per cent.

While the probable efficiency of antiserum for Type II pneumonia and some of the higher types must be admitted, their value has not been as widely accepted as has that of Type I serum and their use must still be considered as somewhat experimental There would seem to be no theoretical reason why, with but few exceptions, specific antisera for most of the types of pneumococci commonly encountered can not be perfected ultimately All attempts to produce a serum effective against Type III pneumonia, however, have been totally unsuccessful to date

It is important to remember that the administration of antipneumococcus serum early in the disease is essential if the most favorable results are to be anticipated This statement is to be interpreted as meaning time in terms of hours not days, after the initial symptoms of onset It is generally felt that a good result may be looked for in cases treated within 24 to 72 hours, and

that up to 96 hours some value may attend the use of serum Evaluation of its effect after 96 hours is extremely hazardous but competent clinical opinion holds that occasionally a life may be saved by serum treatment even this late in the disease

The immediate effects of early and adequate serum treatment are apparent in a critical fall in temperature, relief of dyspnea and cyanosis, relief of intense pleurisy, and disappearance of the symptoms of toxemia in general In cases treated after the disease has been of more than 72 hours' duration favorable results may often be obtained but will generally appear more slowly and are not comparable to those following early treatment In cases with a mild or moderate bacteremia, sterilization of the blood stream, at least temporarily, usually is accomplished

In view of the diminishing effectiveness of serum with increased duration of the disease, pneumonia should be regarded as a true emergency Not only should the value of rapid sputum typing and serum administration within the first few hours of onset be appreciated, but also the relative ease with which this may be accomplished in most communities today should be recognized.

Specific serum treatment of pneumonia cases which have not been typed may be considered justifiable only under unusual circumstances It should be appreciated that serum administration is a major medical procedure which is attended by some risk and should not be attempted unless specifically indicated by typing

Only under such circumstances does the physician have assurance that the procedure will diminish rather than add to the existing hazards of the disease Furthermore serum is so costly that its unwarranted use constitutes a considerable economic waste

There does not seem to be any significant reason for confining serum treatment to persons within certain age groups other than that Type I pneumonia is supposedly infrequent in the very young and the very old Although there are certain difficulties with respect to satisfactory typing and technique of serum administration in children which tend to discourage its use, these can hardly be considered acceptable reasons for withholding a valuable therapeutic agent and usually can be surmounted When serum is given to children an adjustment of the

* For a more detailed discussion of this subject the reader is referred to a recent handbook "Lobar Pneumonia and Serum Therapy" by F T Lord M D, and R Heffron, M D, published by The Commonwealth Fund, New York.

amount on the basis of body weight would seem to be a safe rule

With respect to the technical administration of serum, the following points should be kept in mind

History A history should be taken for evidence of sensitivity. A story of hay fever, asthma or other allergic symptoms indicates caution in testing for specific sensitivity to horse serum or in subsequent serum administration, but need not preclude its use unless these symptoms are of an unusually severe character

Tests for Serum Sensitivity The ophthalmic and the intracutaneous tests should both be employed. If reliance is to be placed on one test only, the latter is preferable. For the ophthalmic test a drop of 1:10 dilution of normal horse serum is instilled into the conjunctival sac of one eye. Conjunctival injection accompanied by itching and burning occurring within fifteen or twenty minutes constitutes a positive reaction indicative of marked sensitivity, and is generally interpreted as a definite contraindication to serum therapy. A violent local reaction may be controlled by the instillation of a drop or two of 1:1000 epinephrine solution

The intracutaneous test is considered somewhat more delicate and difficult of interpretation. This consists of the intracutaneous injection, usually on the flexor surface of the forearm, of 0.1 cc of a 1:100 (sometimes 1:10) dilution of normal horse serum. Normal horse serum seems preferable to the therapeutic serum and is generally provided in the package with it, but in emergencies the therapeutic serum—diluted 1:10 with physiological salt solution—may be used. A positive intradermal test is indicated by a wheal and erythema reaction appearing within twenty minutes. In a case showing a violent reaction to this test serum administration is not advisable. With a mild or slight reaction desensitization may be attempted but should not be undertaken unless proper facilities are at hand

It is important that the patient be watched to prevent rubbing of either the eye or the arm during the interval of these tests since false reactions may be produced if this occurs

Technic of Serum Administration In the absence of evidence of sensitivity by the

above tests serum administration can usually be safely undertaken. The serum dosage, advisability of dilution with salt solution, etc., may vary slightly with different products but the directions accompanying each vial are usually complete and should be followed closely

New York State Serum Concentrated Antipneumococcus Serum, Type I (New York State Department of Health) is now available to physicians throughout the State exclusive of New York City*. The serum is distributed without cost through many of the district laboratory supply stations. A revised list of these supply stations and also of laboratories approved by the New York State Department of Health, including those approved for sputum typing, has been prepared. This list will be mailed to all physicians registered within the jurisdiction of the State Department of Health

The serum is dispensed in vials containing 20 cc (25,000 units). In the package with each vial of serum there is also provided a small vial of normal horse serum, diluted 1:10 in sterile physiological salt solution. This is for testing for sensitivity to horse serum. Also with each two vials of serum the physician can obtain, upon request, a vial containing 10 cc of sterile physiological salt solution. This is provided for further dilution of the horse serum for the intracutaneous test and for rinsing water out of boiled syringes and needles before serum is given. Water in the syringe or needles may coagulate small amounts of serum protein and consequently cause the plunger to stick, or the needles to plug, or may form particles dangerously large for intravenous injection. The salt solution may also be used for dilution of the first small dose of serum given intravenously

This serum is effective, if used early, in the treatment of Type I pneumococcus pneumonia. Its use is not advised for other types of pneumonia or in untyped cases. In the majority of uncomplicated cases, treated within the first seventy-two hours of the disease, the total amount required is about 100,000 units or 80 cc. This is usually given in three injections, the first, actually only a test dose, consisting of 1 cc of serum di-

* Serum in New York City is provided by the Bureau of Laboratories of the City Department of Health

luted with 5 cc to 10 cc of sterile physiological salt solution to facilitate slower and safer administration, the second, given in about one-half hour, consisting of the remainder of two vials (39 cc.) and the third, given after an interval of four to six hours, consisting of two more vials (40 cc.) Continued doses of 50,000 units (40 cc.) should be given at four to six hour intervals if the first 100,000 units fails to produce the desired result. It is doubtful, however, that amounts totaling over 200,000 to 250,000 units have any additional therapeutic value and the use of such quantities is not generally recommended.

This serum is prepared for intravenous use only. It may be given either directly, without dilution (save of the initial test dose as recommended) or may be given in variable quantities of salt solution suitable for intravenous use. All serum and salt solution so given should be maintained at body temperature throughout injection and should be administered very slowly, at a rate not in excess of 1 cc per minute on the basis of the amount of concentrated serum present.

The attention of the physician using New York State serum is called to two forms (1) the application form which should be filled in by the physician or messenger before serum is taken from the supply station, (2) the short report form (supplied with each vial), one of which should be fully filled out and returned at the completion of treatment of each case.

It can readily be appreciated that only by means of such records can an adequate evaluation of the extent, character and results of serum treatment be obtained. Not only is such an evaluation of importance to medical progress but it is essential to the continued distribution of such a costly product and will in a large measure determine whether or not the Division of Laboratories and Research shall attempt to expand its facilities for serum production and distribution in the future.

Epinephrine Throughout the process of testing for sensitivity and serum administration, a hypodermic syringe containing 1 cc. of epinephrine solution (1:1000) should be kept filled and ready for immediate use.

Serum Reactions These may be classified under three types for the purpose of discussion.

The *acute anaphylactic* reaction is extremely rare if the proper precautions are observed. The first indication of such a reaction may be a sense of substernal pressure or difficulty in breathing, gradually increasing to frank dyspnea with cyanosis, increasing bronchial spasm and pulmonary edema, or a sudden rise in pulse rate with a decrease in pulse volume, or the occurrence of abdominal or lumbar cramps, or generalized urticaria. Following the initial symptoms collapse and death may occur within a matter of seconds. This type of reaction constitutes an emergency which fortunately is very seldom encountered, but for which the physician should always be on the alert. The immediate cessation of serum injection and prompt injection of epinephrine either intramuscularly or intravenously, as the urgency of the case indicates, may prevent an otherwise disastrous result. The anaphylactic type of reaction may occur within a few seconds to one-half hour or so after the administration of serum, the more violent reactions, however, usually occur within a few seconds or minutes.

The *thermal reaction* is characterized by a chill and fever generally occurring in from one-half to one hour after serum administration. Such reactions are usually self-limited and require only symptomatic treatment. It is wise, however, to watch the temperature closely and if it rises to too high a point to take measures to bring it down since fatalities attributed to such hyperpyrexia have been described. The occurrence of this type of reaction, unless unusually severe, is not considered a contraindication to further serum treatment.

Typical *delayed serum sickness* characterized by fever, urticaria, swollen glands, and painful joints may develop at any time from four to ten days subsequent to injection, even considerably later in some cases. Though it causes the patient a good deal of discomfort, it is not considered serious and generally requires only symptomatic treatment. With the new concentrated and purified serum this type of reaction is much less frequent and milder than formerly.

Nursing Care It is generally conceded that skilled nursing care has favorably tipped the balance between life and death in many pneumonia cases. In pneumonia probably more than any other disease good nursing judgment is essential. The key to

good nursing care and the results it brings is probably included in the one word *rest*. Rest does not mean neglect. It is attained by a delicate distinction between essential and excessive care, which varies with each individual case.

Isolation The fact that pneumonia is, to a certain extent, communicable should be kept in mind. Attention should be given to the safe disposal (boiling or burning) of all respiratory secretions and articles contaminated with them, to protection from direct exposure to the patient's cough, to the use of an apron or gown by the attendants in the sick room, to careful washing of hands after caring for the patient, and to a thorough cleaning of the sickroom, bedding, etc., after the illness. Visitors should be kept out of the room insofar as possible for their own sakes as well as the patient's and, of course, small children and elderly persons should be kept out entirely.

Prophylactic and Therapeutic Vaccines, Treatment with Diathermy or Pneumothorax These and other technics in the vanguard of experimental work, are widely discussed in the scientific literature of the present day. They must be considered matters unquestionably worthy of serious study but hardly sufficiently established for general adoption at present.

Course

Lobar pneumonia will usually proceed to recovery or death in from five to ten days. Recovery may occur either by crisis or lysis. In a recovered case resolution proceeds without any definite rule as to duration. Early and adequate serum treatment should result in recovery by crisis within a few hours. Occasionally, however, recovery by lysis will occur. The course of resolution is not altered in these cases unless serum treatment be given early enough to prevent much consolidation occurring.

Death from acute pneumonia is often difficult to ascribe to its immediate source. General circulatory failure is certainly a frequent terminal event. Asphyxiation and respiratory failure sometimes seem to play a part. Septicemia may lead to meningitis, acute bacterial endocarditis or pericarditis which are very likely the specific causes of death in such cases. Frank cardiac failure is uncommon in cases not previously cardiac in nature.

Prognosis

There are six recognized factors which alter the outlook in any given case. These are (1) the age of the patient, the outlook being more unfavorable at the extremes of life, (2) the type of organism causing the infection. Among pneumococcal pneumonias (not serum treated) Type III is reported as having a case fatality rate of about 50 per cent, Type II about 40 per cent, Type I, 30 per cent, and the massed higher types 30 per cent. Hemolytic streptococcus pneumonia is always serious having a fatality rate of somewhat over 50 per cent in inter epidemic periods and much higher, of course, during the epidemics such as that of 1918, (3) bacteremia early in the disease makes the prognosis more grave, and persistent bacteremia makes it very poor indeed, (4) if serum treatment is instituted the duration of the illness before treatment was started materially influences the prognosis, (5) the presence of cardiovascular disease or any other chronic debilitating condition makes the outlook less favorable, (6) an inadequate leukocyte response is among the worst prognostic signs. An inadequate febrile reaction, disproportionate to the other clinical evidence of infection, may be similarly interpreted in most instances.

Convalescence

It is well to remember that the patient who has recovered from lobar pneumonia has recovered from an extremely severe illness. The myocardium is likely to be weakened as well as the entire system. Accordingly, time spent in an adequate convalescent course is time well spent and actually time saved.

Complications

The more important complications which may contribute to a recurring, or sustained fever and delayed recovery are empyema, serum sickness, acute and sub-acute sinusitis, otitis media, mastoiditis, thrombophlebitis, and reactivated pulmonary tuberculosis. Suppurative lesions such as pericarditis, pneumococcal pyoarthrits and ischiorectal abscess are occasionally encountered.

Overwhelming pneumococcal septicemia, meningitis, and endocarditis, when encountered, are usually terminal events.

Delayed resolution may progress into chronic pulmonary fibrosis and bronchiectasis in certain instances. This seems par-

ticularly true in cases of influenza, streptococcus, and whooping cough pneumonia

Icterus is fairly common Unless of unusual severity it does not seem to alter the prognosis Auricular fibrillation may appear for the first time, especially in elderly patients and may, or may not, be evidence of serious cardiac damage The danger of

embolism is always present though it is not frequently encountered In elderly people mild cerebral accidents may occur during the height of the disease which cause a prolonged comatose or semi-comatose state during convalescence Transient postpneumonic psychosis may develop after the subsidence of the acute disease

A HISTORY OF MEDICINE IN THE STATE OF NEW YORK AND THE COUNTY OF MONROE

FLORENCE A COOKSLEY, B A , M A , Rochester
Librarian, Rochester Academy of Medicine

Part II History of Medicine in Monroe County

Chapter IV

The Rochester Academy of Medicine
and

The Rochester Medical Association

Formation of Rochester Academy of Medicine 1900, Medical Library of County Society continued by Academy and Reynolds Library Academy rents a home Rochester Medical Association formed 1914 Home purchased Financial success, Assumes control of library, Medical School gets part of library, New home purchased, 1923, Amalgamation of Academy and Association, 1929

The advisability of establishing a medical library was earnestly discussed at the seventy-first meeting of the Monroe County Medical Association on May 27, 1891 and upon motion of Dr F F Dow, the president appointed a committee of three, Dr Dow, Dr Angell, and Dr H S Durand, to consider the question and to report at the next meeting. At the annual meeting the following year the Committee reported that the Reynolds Library Committee expressed a willingness to assist in maintaining a medical department as an addition to the library. A resolution was passed by the County Society that the Library Committee of that society should be authorized to receive donations of medical literature and of funds to be expended for such literature and that the Committee be further authorized to make such arrangements with the Reynolds Library as in their judgment might seem best. Fifty dollars from the treasury was voted for the annual use of the Committee and the president, Dr Edward W Mulligan, appointed the following Committee, Dr F F Dow for one year, Dr Harriet Turner for two years, Dr Sarah R. A Dolley for three years, and Dr John O Roe and Dr Edward B Angell for four years. In the following year Dr Dow was re-appointed, this time for a term of five years and all succeeding appointments were for that length of time.

In 1897 Dr Angell reported for the Li-

brary Committee saying that there were on file at the Reynolds Library all the leading medical papers in the world. An additional fifty dollars was voted for the library as the Society had been unable to give anything during the past two years due to a lack of funds. The report of the Committee stated that in 1892 the Reynolds Library had agreed to contribute to the medical department of the library, an amount equal to that given by the Medical Society up to \$250 00. Fifty dollars had been appropriated by the medical Society and \$100 00 contributed by the members and the Reynolds Library therefore gave \$150 00 and of the \$300 00, \$250 95 had been spent mostly for periodicals, sixty of the most important English, French and German journals being subscribed for. The report of funds expended was given as follows:

	Fund	Expended
1895-6	\$285 85	\$260 03
1896-7	\$485 02	\$450 85
1897-8	\$384 17	\$253 90
1898-9	\$330 37	\$321 20
1899-'00	\$569 07	\$472 55
	<hr/> \$2054 48	<hr/> \$1758 53

It had long been felt that the medical profession should have a home of its own but all attempts to establish such a home had come to naught. With a growing library to be cared for, it became more evident than ever that permanent headquarters were needed. A letter signed by Drs William S Ely, John O Roe, and Edward B Angell

* Continued from December 15 issue.

was therefore sent to the medical men of Rochester, saying, "It is proposed to organize an Academy of Medicine in Rochester and you are invited to attend the preliminary meeting to be held on Monday evening, June 26, 1899 at 8 30 P M at the Reynolds Library, to discuss the advisability of the project." Twenty-three physicians attended the meeting, which was called to order by Dr Angell after which Dr Ely was chosen chairman, Dr H T Williams acting as secretary

Dr Angell "explained the object of the meeting was to form a society to be known as the Rochester Academy of Medicine and to be a society for scientific work" and for social purposes only incidentally All present were in favor of the project and a committee, consisting of Dr Roe, Dr Angell, and Dr E H Howard, was appointed to draw up a constitution

By-laws were formally adopted on January 24, 1900 and the officers elected were, president, Dr William S Ely, secretary, Dr H T Williams, treasurer, Dr Edward B Angell, councilors, Dr E H Howard, Dr E W Mulligan, Library Committee, Dr J O Roe, Dr J L Rosebloom and Dr E B Angell While the minutes do not state who were charter members, we assume that they were as follows

Those attending the first meeting were

Dr W S Ely
Dr J F W Whitbeck
Dr John O Roe
Dr Edward B Angell
Dr Robert Cook
Dr J L Rosebloom
Dr E H Howard
Dr Lewis W Rose
Dr Sumner Hayward
Dr S L. Elsner
Dr C A Dewey
Dr E W Mulligan
Dr William R. Howard
Dr Ezra B Potter
Dr Charles E. Darrow
Dr E. Wood Ruggles
Dr Nathan W Soble
Dr M S Collier
Dr William L Conklin
Dr Charles D Young
Dr Thomas A O'Hare
Dr Charles S Starr
Dr Henry T Williams

Those attending the second meeting, adopting the by-laws—(besides any of the above)—

Dr Charles R. Barber
Dr W M Brown

Dr Marion Craig Potter
Dr George M Goler
Dr A W Henckell
Dr William B Jones
Dr E. M. Moore, Sr
Dr E M Moore, Jr
Dr J A. Stapleton
Dr T O Tait
Dr Robert L Carson
Dr Joel M Ingersoll
Dr Frederick W Zimmer
Dr Louis A Weigel
Dr S Case Jones
Dr Charles T LaMour
Dr E V Stoddard
Dr Eveline Ballentine
Dr Frank A. Jones
Dr Henry Koch
Dr J W McGill
Dr H J Mann
Dr D G Mason
Dr Wheelock Rider
Prof Charles W Dodge
Prof. S A. Lattimore

The membership of the newly founded Academy was divided into four sections, (1) General medicine, (2) Surgery, (3) Obstetrics and gynecology, (4) Public health The chairman elected by these sections were vice-presidents of the larger body At the following meeting, February 7, the treasurer reported that thirty-three fellows had paid their dues of \$20 00 each

The first annual meeting of the Academy was held on December 12, 1901 in the Hall of Reynolds Library The retiring president, Dr William S Ely stated in his annual address before the Society that he had long contemplated the desirability of establishing such an organization He enumerated the advantages it might promote as (1) the maintenance of a high standard of professional relations in a period when a commercial spirit seemed manifest in the profession, (2) stimulation of study and original research, (3) the fostering of a medical library and the preservation of valuable medical contributions, (4) by dividing the work of the Academy into Sections, to enlist the interest of the growing number of specialists in important branches of medicine, and (5) to make known the need of a permanent Academy building or home for the profession of a large and growing city He explained for the benefit of those who considered the fees and dues too large, that they were necessary to maintain the Society on a plane consistent with its dig-

nity and importance and that the members received in return for these dues the advantages of the Academy and the library and that with the aid of the Reynolds Library which gave an equal amount subscribed by the Society, the library was being built up. Meanwhile there was being accumulated a permanent fund which with gifts from the outside would ultimately provide a permanent home.

President Ely's address contains so much of interest that we will quote freely from it.

Now, Fellows of the Academy, is it reasonable to attempt to forecast the future of such a body as this and from our present beginning, looking down the years, to see an Academy of Medicine in Rochester of hundreds of active and scientific workers of the highest character and aims, assembled in a completely appointed structure owned by the members of the profession, built and endowed by their patients and friends, who in a common faith are devoting themselves to the welfare of humanity? To your Council this dream does not seem too visionary and I am confident that it may be realized in the lifetime of some of those present, if we unite in a faithful devotion to the permanent interests of this organization. Other cities have costly homes for their Academies of Medicine, why should not Rochester also possess among its numerous educational structures one to be known as the Rochester Academy of Medicine? As our eyes from week to week are caught by its Seal, let that Seal remind us that the Rochester Academy of Medicine needs and must have its permanent home.

It is regrettable that this earnest founder of the Academy did not live to see the realization of his dream, for he died in 1911. The first building was purchased in 1914.

After the remarks which we have quoted, Dr Ely proceeded to speak of some diseases which were then little understood. He said that it was a good thing that patients did not know how ignorant their physicians were regarding the causes and treatment of pneumonia, nephritis, cancer, diabetes, progressive pernicious anemia, Graves' disease, epilepsy, and other diseases. He said that the treatment of all these was unsatisfactory. He added that cancer was practically proven to be a parasitic disease and that the latest suggestion regarding diabetes was that it is of an infectious character and that all they could do was

to modify the patient's diet so as to keep the urine free from sugar and at the same time maintain the body weight, but diabetes was incurable, treatment being only for symptoms and life prolonging. In exophthalmic goiter, he added, they were dealing with an obscure affection of the nervous centers of which they were ignorant. He concluded, "Only in recent years have biological chairs been equipped in the colleges and the benefit just being reaped. There is now no place in the science of medicine for the unbiological physician."

We are interested in Dr Ely's address because of the changes in medicine since then and also because of the enthusiasm which he expressed as the representative of fifty equally enthusiastic members, for building a permanent home. With the large dues collected and the determination of the members, we would naturally expect that a building would be forthcoming. We are therefore surprised to find that the Academy of Medicine, like the Monroe County Medical Society and the Pathological Society, failed in this project and that it remained for a later organization, the Rochester Medical Association, to succeed in purchasing a home. We will tell that story later. One thing should be borne in mind in discussing these various medical societies and that is, that the membership of these organizations consisted of almost the same men, with only the leaders different and even they were identical in many instances. Each society had its own function and well-defined motives and when they merged into a common organization, it was because their functions had become the same.

Soon after the formation of the Academy of Medicine, the Monroe County Medical Society ceased to give toward the library fund. In 1900, the year of the founding of the Academy, the Monroe County Society gave one hundred dollars and the Academy gave one hundred fifty dollars. That was the first time, and also the last, that the Reynolds Library had to give the full amount of its pledge, two hundred fifty dollars. All other times, the amount was considerably less. That year, 1900, the medical library consisted of 2,056 volumes. Many of these books were gifts from physicians, also, there were 1,357 volumes including a complete set of Virchow's *Archiv*s, which had been presented to the

Academy by the New York Academy of Medicine. Dr Roe and Dr Angell had gone to New York City in July of that year and had gone into the hot dusty basement of the New York Academy and had chosen the volumes, for a nucleus of the new library. The set of Virchow's Archives, which the members considered so valuable and were so happy to own, became temporarily the cause of bad feeling, for when the library of the University Medical School was being assembled, this set of books was given to the Medical School by the Reynolds Library, without first getting the approval of the Academy. How the division of books which had been the joint property of the Academy and of Reynolds Library came about, so that the new medical school received a part of them, will be explained later when we tell of the property purchased by the Rochester Medical Association and the housing of the library in the new building.

To return once more to a consideration of President Ely's enthusiastic address, one benefit resulted therefrom which brought much joy to the membership. Dr Ely announced at the meeting in the following November, that a patient of his, Mr Charles T Ham, had read that address and greatly interested, had presented the Academy with a check for five thousand dollars. Mr Ham was hailed as the first benefactor of the Academy and it was the hope of its members that more public-spirited citizens would contribute to the building but no further contributions from laymen were received.

The bookplate of the Academy of Medicine, adopted in 1904 was the same as used today, with the motto, "Ars Medica Crescat," "Let Medical Science Flourish." At the meeting which we have just reported there was an interesting discussion of the desirability of having a building of its own but nothing was really done until 1910 when a motion was made to purchase the Luitweiler homestead at 128 East Avenue and the motion having been carried by a vote of fifty-one for and nineteen against, a committee on arrangements was appointed consisting of Dr Williams and Dr Roe. The Academy then had in the treasury twelve thousand dollars. However the purchase was not consummated. Eighteen months later, on January 17, 1912, Dr Ralph Fitch again brought up the question

of a permanent home and a new committee was appointed consisting of Dr Edward B Angell, Dr Edward Mulligan and Dr Willis E Bowen. The committee reported soon after, recommending that ten thousand dollars be set aside as a permanent library fund, invested to secure five hundred dollars per year for the upkeep of the books and that the membership be increased by fifty members to obtain the needed funds. A discussion followed regarding the advisability of renting a home on East Avenue owned by Dr Fitch, the upper floor of which he would rent for six hundred dollars a year. The committee reported that it would cost about two thousand dollars yearly to take care of the rooms and the library.

Letters were then sent to the members asking for opinions regarding that proposition and many replies were received. Forty-seven were in favor of increasing the membership, eight opposed, twenty-eight Fellows agreed to contribute a total of \$350.00 annually besides regular dues. It was then decided to rent the lower floor of the Fitch home for the sum of one thousand dollars a year, with care included. Partitions in the new quarters were removed and the three large rooms were leased for three years from May 1, 1912. On January 14, 1914, Dr Hanes read the following report from the Council of the Academy.

In the early months of 1912, following an individual canvass of the Fellows, the Academy of Medicine embarked on a new enterprise in its history, that of maintaining its own home. It was appreciated that we had not sufficient means to purchase and maintain a home, so it was decided as a result of that special canvass of the Fellows, as expressed on several occasions through the medium of the ballot at meetings called for that purpose, to own our own home, it was the hope of those responsible for the formation of this plan that this temporary rental period might serve as an evolutionary stage in the process of acquiring a permanent home for the Academy and that this temporary home would serve to crystalize thought and activities and in turn, lead to the acquisition of permanent quarters. There have been many differences of opinion among our Fellows during the past two years relative to the wisdom of the present plan of a temporary home, some feel that the location is not sufficiently central, others that the expense is too great, etc., so that with its present knowledge, your Councilors feel

quite unable to interpret the general thought of the Academy on the subject of an Academy home. In a recent effort to clarify the situation, if possible, a letter of circular character was sent to each Fellow, with the request that the financial extent to which the individual Fellow would be willing to assume responsibility for the purchase of a permanent home under ideal conditions, be indicated. We are unable to report any decisive result from this effort but twenty-seven replies having been received to this inquiry, only twelve of which were in any degree indicative of a willingness to assume individual financial responsibility on the part of our Fellows toward the purchase of a permanent home.

It is somewhat difficult at first, to clearly follow the history of these various medical societies in Rochester and not get them confused. Their paths seem at times to run parallel, then merge, sometimes becoming permanently one, sometimes diverging again in quite different directions. Let us try to make their individual existence a little clearer before starting the study of the development of the Rochester Medical Association and then follow with the resumption of the story of the other societies.

The Medical Society of the County of Monroe is the oldest medical society in Rochester and has continued with little change in general structure through the years. The Rochester Pathological Society came next, functioning as a scientific and social organization, first as a separate individual society, then later as a section of the Academy of Medicine. As the County Society became more active in local, county, and state medical affairs, with the Academy assuming much the same function, the Pathological Society gave up such activities and indulged in scientific meetings followed by a social hour. Although this organization is a part of the Academy according to constitution, its by-laws requiring that candidates for membership must first be members of the County Society, remain unchanged. The Rochester Medical Society, the third society to be formed, was born early, lived abundantly, and quickly passed away. The Academy of Medicine, created because of the need of founding a library, became a spirited scientific organization of high repute but limited in its membership by its by-laws. This very limitation caused the rise of a new medical society, called the Rochester Medical Association.

With meetings similar in nature, the two societies, the Academy of Medicine and the Rochester Medical Association, met in the same building, the property of the latter society, until with membership and purpose so much alike and with too many meetings to attend with comfort, it was decided to amalgamate. How this amalgamation came about, we will explain by discussing the origin and work of the Medical Association. Having done that, we will try to show the special work done by each medical society.

As has been stated, the Rochester Academy of Medicine was limited in its membership. The young men of the profession were not admitted, a certain maturity and experience being required, together with a scientific paper to be submitted with the application for membership. There was a still more serious obstacle to certain members of the profession. Attention has been called in the discussion of State medical history, to the abrupt break in the membership of the State Society, brought about by the adoption of a new code of ethics, caused in turn by the growing power of the Homeopathic and Eclectic practitioners, who had been treated as pariahs. Many members of the old State Society left its ranks and formed a new one. Likewise new County societies were formed. In Rochester a County Homeopathic Society was formed in 1866 with seventeen charter members. In 1907 there were seventy-four physicians practicing homeopathy in the city with two homeopathic hospitals operating successfully, the Homeopathic Hospital, now the Genesee Hospital and the Hahnemann Hospital, now known as the Highland Hospital. The former was opened in 1889 and the latter in 1891. Some of the most highly respected practitioners of Rochester were of this school and less than half a dozen had been admitted to membership in the Academy of Medicine.

There was another society of physicians called the Hospital Medical Society, organized in 1898, which had for its active members, only those who had practiced for less than fifteen years. We will speak of that society later. Although there were many medical societies, the Monroe County Society, the Pathological Society, the Academy of Medicine, the Monroe County Homeopathic Society, the Rochester Hahnemannian Society, the Blackwell Medical

Society for women physicians, and the Hospital Medical Society, there was no strictly scientific medical society open to all practitioners. It might seem a plethora of organizations to add another medical society to the already long list but as we shall see, this new organization was able to satisfy the needs of the other societies and so came to absorb most of them.

At a special meeting on January 22, 1914, called by the members of the Rochester Pathological Society, Dr. Frank Burr Tibbals of Detroit gave a stirring address, telling the assembled members of the Society and other invited medical men of the city, of the medical home in Detroit and the possibilities of a similar organization in Rochester. At the end of his paper, the meeting was adjourned and reassembled to form the Rochester Medical Club. (The name Rochester Medical Association was adopted at the following meeting.) Dr. W. D. Ward acted as chairman of the meeting and Dr. Charles Hinchey as secretary. All present expressed a desire for such an organization and a committee composed of Drs. W. B. Jones, W. L. Bowen, Charles R. Barber, Kathleen Buck, Ralph R. Fitch, William W. Percy, J. K. Tretton, W. Douglas Ward, and David B. Jewett, was appointed to consider its formation. After a number of meetings of the committee to consider ways and means, a meeting was called at the Chamber of Commerce on Friday, February 13, 1914. About one hundred fifty physicians attended this meeting and elected as officers to serve until May 1, 1915: president, Dr. W. B. Jones, vice-president, Dr. F. F. Dow, secretary, Dr. D. B. Jewett, treasurer, Dr. Wesley T. Mulligan, board of directors, Drs. J. O. Roe, J. R. Calkin, E. J. Bissell, H. T. Williams, W. D. Ward, V. A. Hoard, W. I. Herriman, L. L. Button, and M. B. Palmer.

The object of the Association, as stated in the constitution was (1) the acquisition and maintenance of a building with assembly, committee, and social rooms, for the use of its members and for preserving the archives and effects of the Association and its Sections, and such other purposes as are incidental to or connected with such object, (2) the advancement of the science and practice of medicine and surgery, the promotion of sanitation and public health,

the maintenance of a library and of allied arts and sciences, (3) the promotion of the activities and interests of societies of similar character allied with it.

The constitution was adopted on March 30, 1914 and all who signed within thirty days were considered charter members. Two months later (June 1) there were about one hundred sixty members who had subscribed the sum of \$18,700.00. The Jeffrey property on the corner of Chestnut and Euclid Streets was purchased for \$35,000.00. A first mortgage was given to the Rochester Trust Company for \$23,000.00 and a loan of \$10,000.00 obtained from the Merchants Bank. We will show later how this property, bought in 1914 for \$35,000.00, was sold ten years later for \$100,000.00, the loan of \$10,000 having been paid off in the meantime. The Association was served by Dr. W. Douglas Ward as treasurer almost from the time of its organization until his death in 1936 and the secretaryship has been held since 1922 by Dr. Harry Clough.

The membership of the new medical society grew rapidly and in October, five months after its organization, there were 286 members. The annual dues were \$15.00 and there was usually a favorable balance except in the year 1919 when it was found necessary to make an assessment of five dollars.

We have shown the origin of the Rochester Medical Association and its rapid financial success. Let us look back to what happened in the Academy of Medicine during that time. The minute book of the Academy reports the founding of the Rochester Medical Association and approval of the project. The members voted to become a section provided that the Association take over the library, provide a librarian, and care for the books. A committee was appointed to consult the trustees of the Reynolds Library regarding the share that library had in the Academy collection. Despite this action, the Academy never became a section of the newer body but did hold its meetings in the Association home as soon as it was opened.

According to the minutes of the Academy, Dr. Jewett acted as an intermediary between the two societies, presenting to the Academy members the purposes and practices of the other organization. In February 1915, the Academy received a com-

munication from him, as secretary of the Association, stating that it was the hope of the Board of Directors that every member of the medical profession would find in the various sections an opportunity for social and scientific work and more cordial personal and professional relations would be developed. In order that the scientific work should be enhanced, it was the purpose of the Board of Directors to invite distinguished men to address the Association at large.

The new medical society, the Rochester Medical Association, became a melting pot for all interests in the medical profession. This was soon shown by the large attendance at the monthly meetings. In May 1915, the members of the Academy had a serious discussion at its meeting, regarding the large attendance at the Association meetings, about two hundred attending, whereas the attendance at Academy meetings had dwindled to twenty-five persons. There was some feeling expressed that the Association had not adhered to its original plan and was holding scientific meetings in competition with the Academy. Finally a motion was carried that it was the sentiment of the Academy that the Association should continue its scientific meetings, that all were concerned in the greatest good.

In the meantime, the Sections of the Academy continued to hold their separate meetings and in October 1916, there was a discussion at the Academy meeting regarding the advisability of discontinuing these Sections. It was said that the Academy had been organized after the style of the New York Academy of Medicine, in a city where there were many specialists but in Rochester there were not fifty strictly specialists in the list of four hundred fifty physicians. It was decided, however, not to make the change at that time.

The next important question to be considered by the Academy members was the maintenance of the library. The Reynolds Library trustees had agreed to transfer their share in the medical collection if the Academy would repay the money expended upon the books and binding by that Library (\$3,784.22). This the Academy seemed unwilling to do. Now came the University Medical School with its need of a good medical library and some of the Academy members recommended that all the volumes mutually owned by the Academy

and the Reynolds Library be turned over to the school. Mr. Donald Gilchrist, Librarian of the University said at the meeting where this was proposed, that the medical library of the University was to be housed at the medical school and would be a 100,000 volume library. Sixty thousand dollars were to be spent on complete sets of old periodicals and nothing the Academy voted to do with its library would affect the plans of the University. If the Academy had any books that the University could use, it would be that much money saved, but Dr. Whipple, the new Dean of the Medical School would not accept any conditional gifts.

Dr. George Goler, a member of the Academy, said that the people of Rochester was not a reading public and that it was necessary to blow the dust off the medical books in Reynold's basement if anyone wanted to use them. He advocated giving them to the University. Dr. James Quigley, another member, thought that the journals should be kept at the Association rooms for at least two years before giving them to the medical school. Some thought that the medical school library would be too inaccessible to be of much use to the practitioners of Rochester. Mr. Yust of the Rochester Public Library system thought, too, that the Academy books should go to the University. Many of the older members of the Academy were hurt and chagrined because the library for which they had labored so long and which was the original cause of the organizing of the Academy of Medicine, should be held lightly as if of little value, by the University authorities and that some of the members themselves should be willing to give it up. General Noble of the Surgeon General's library in Washington, addressed the meeting that night, March 8, 1922, speaking on the subject of Local Medical Libraries. General Noble pointed out that there are three chief requisites of a library, first, books, second, housing, third, service. Without service you have a dead library. He thought there should be a library at the medical building where the members would feel at home, rather than at the University where they would feel out of place. He thought, moreover, that it was a function of the Academy to educate the public in medical matters.

This meeting occurred in March 1922.

and in May both the Academy and the Association again discussed the question of the future of the library. The Academy and the Association were working together in providing for the library and continued to share in this work up to the time the two societies amalgamated. It was decided to offer to Dean Whipple of the Medical School, such books and journals as he should desire for the medical library he was developing. The Academy was to relinquish its claim to its share in the books at the Reynolds Library, providing the Reynolds Library did the same. It is interesting to note that the trustees of the Reynolds Library who had refused to give their share in the books to the Academy, unless repaid for the sum that library had expended, now were quite willing to give them to the University.

After the University had removed the volumes desired, those remaining were catalogued, this cataloging costing \$869 13, about one hundred dollars of which cost, however, was for necessary furniture. The Association paid most of this expense. The library having been moved to the new building of the Association, a trained librarian, Miss Frances Joiner, who had been doing the cataloging, was employed as librarian and served in that position until 1928.

And now came the next change, the buying of the second and permanent home of the Association. An offer of thirty-five thousand dollars made in 1919 for the Chestnut Street building had been refused, as that was the price paid for the building and there was no reason for selling. The next offer came in 1922 when a price of \$72,000 too was rejected. The next offer, unsolicited as were the others, came in 1923, of \$90,000 00 and the trustees began looking around for another home. At the end of that year a final offer of \$100,000 00 was accepted and the present quarters at 13 Prince Street was purchased from Mr. James S. Watson for \$50,000 00. It had formerly been the property of a Presbyterian minister and was in excellent condition. The building was remodeled to fit the needs of the Association, redecorated and furnished and when all bills had been paid, the Association had a beautiful home, free from debt and \$9,500 00 in the bank. Few of those who now enjoy the comfort and

facilities of the library and the building in which it is housed, appreciate the long years of planning and giving which were necessary before this triumph was achieved.

The two societies, so similar in function, continued to hold monthly meetings in turn and both working peacefully together in building up a fine library, each paying toward its support. Let us not get the idea that the maintenance of the library was the only function of the two medical organizations. It was an important and perhaps the chief function, however, each society enjoyed splendid scientific programs, bringing many noted medical speakers to the city. But gradually the membership became more and more identical, with the same purposes in mind. There came the recurrent cry of too many medical meetings to attend and too many societies to support. In the Spring of 1929, committees of the two groups met together to discuss amalgamation. This union was quickly brought about. The type of organization which the Association had adopted, was deemed less cumbersome than that of the Academy and was therefore adopted for the united societies. The Association disbanded and both organizations turned over their treasures and property to the new society, which received its charter under the name of the older group, the Rochester Academy of Medicine. The officers elected at the last meeting of the Association in May 1929 became the officers of the new society. To most of the members, there was no visible change, the chief difference being one less meeting each month and the dues of one society eliminated. We are impressed with the fact that every time there is a strong complaint against too many meetings, the complaint is directed against the large societies. The Sections of the Academy were eliminated and then small groups of pediatricians, roentgenologists, obstetricians, and others began to hold regular meetings. Then each hospital began monthly, even weekly meetings of staff members and again came discontent with too many demands upon the time of the medical man. Frequently comes the suggestion that three large medical societies are too many for Rochester and too many to support. The younger members often direct their attack against the Academy, not knowing that it is the membership of the

Academy that owns and supports the Academy building and that all the other groups, large and small meet in that place through the courtesy of its members and without contributing toward its support. To abolish the Academy would mean to hand over all its assets to the Monroe County Society, which must continue because of its State and National affiliations. Moreover, the two organizations are too dissimilar in nature for amalgamation at this time. The County Society is more active in protecting the medical profession from unjust and harmful laws propagated by ignorant laymen and in keeping a watchful eye upon

public health conditions, working as ever for health preservation and disease prevention. The Academy leaves these matters to the care of the County Society and concerns itself with scientific and educational programs and with the maintenance of the building and its library.

We must leave this discussion of the larger medical groups—the Monroe County Society, the Academy, and the Pathological Society—to examine the origin and function of some of the smaller medical societies of the city, which filled a particular need and successfully functioned until that need no longer existed.

Chapter V

The Smaller Medical Societies and Conclusion

Homeopathic groups in Rochester The Hospital Medical Society The Blackwell Society Rochester Free Dispensary Women's State Medical Society Recent work of County Society, Outstanding member Dr E Mott Moore Conclusion

The stronghold of Homeopathy was in New York City but Rochester had a considerable number of that school. There were two homeopathic societies in this city, the Homeopathic Medical Society of Monroe County and the Rochester Hahnemannian Society. The County group was organized January 2, 1866 with seventeen charter members. The first officers were Dr George Lewis, president, Dr M M Mathews, vice president, Dr D A Baldwin, secretary-treasurer. In 1884 there were thirty-seven members and in 1907, fifty-two members. That year there were eighty-eight homeopathic physicians in Monroe County, seventy-four of whom lived in Rochester. The Hahnemannian Society in 1907 had seventeen members. The latter society had been formed in 1886 by seven homeopathic physicians of Rochester, who felt that the County Homeopathic Society membership was diverging from the true Hahnemannian principles. Its president and ardent leader was Dr Joseph A Bigler, vice-president, Dr R A Adams, secretary-treasurer, Dr R C Grant. Space does not allow us to include the transactions of the State Homeopathic Society and therefore those of the County and City Societies cannot be included, for it would not be possible to well understand one without the other.

Mention was made earlier of the Hospital Medical Society, another organization

of medical men of Rochester which served a particular need while the need endured. The younger practitioners of the city were not admitted to membership in the Rochester Academy of Medicine, and in order that they might meet together for purposes of study and for the promotion of professional friendships, they formed the Hospital Society in 1898. Only those in practice less than fifteen years were admitted to active membership and this rule was rigidly enforced. A member having reached his fifteenth year of practice became an honorary member, henceforth "to be seen and not heard." The active members were never great in number and most of them were interns or on the staff of the City Hospital. Many of the physicians who later became leaders of the medical profession in the city, had been officers of this group. With the organizing of the Rochester Medical Association open to all licensed practitioners, the need for such an organization ceased and as many of its members left the city for service in the World War, meetings gradually ceased. Physicians of the city today who were among the youthful members of the Hospital Society speak of that group with a warmth of feeling in appreciation of its informal meetings with its excellent papers and lively but friendly discussions.

Another medical society should be rec-

ognized as having done a particular good in the county, the Practitioners Society, later called the Blackwell Society, an organization of women physicians of the county and vicinity. It grew out of a need for a dispensary for the poor. Before this dispensary had been formed in 1886 by the women physicians of Rochester, there had been a clinic, Rochester Free Dispensary, which existed from 1872 to 1879. Let us note briefly the part this organization played in caring for charity patients of the city.

The only information remaining of this clinic is the secretary's book recording meetings from February 21, 1875 to October 10, 1877, with an addenda written in 1914 by Dr Charles S Starr, a charter member. Dr Starr from his recollections wrote a history of the Dispensary in the addenda and stated that no record but this book remains.

On August 1, 1872, just one year after its organization by eight physicians of Rochester, a suggestion was made at a meeting of the Rochester Pathological Society that a Dispensary be established. The Dispensary was opened soon afterward at 12 Mill Street. On February 21, 1873, according to the first minutes in the book, the Board of Managers of the Rochester Free Dispensary met at the office of Mr E M Smith and after transacting such business as pertained to the old organization, adjourned "sine die" and the Board then reorganized under the charter.

From the by-laws we learn that the Dispensary was founded and put into working order by the personal efforts and private means of the Pathological Society and citizens of the city. The attending medical officers were active members of the Pathological Society and the consulting officers were active or honorary members of that Society, each serving in rotation for three months. These men had been in practice for ten years, five of which had been spent as active members of the Society and as attendants at the Dispensary for two years. None of them received compensation for their services. At first there was a fine attached for absence from assigned duty but this was found inexpedient and those reluctant in serving, were dropped from membership. No doubt, the work required too much from the busy practitioner and

one by one, they resigned but there was always someone willing to be elected to fill a gap. The Dispensary opened at first for one hour each afternoon except on Sunday and holidays and later an hour in the morning was added.

Laymen served as members of the Board and one of them, Mr Ezra Andrews was treasurer for the eight years the Dispensary existed. The funds to start the clinic were solicited by members from citizens of the city and druggists at first contributed medicines. In 1873 the members asked the Common Council for a contribution of \$500 00 and for permission to meet in what was called the new Center Market Building on Front Street. Both requests were granted. With this gift from the city and with \$425 00 which had been solicited, the Dispensary was soon well-equipped and after all bills had been paid, there remained in the treasury, a year later, the sum of \$300 00. In July of that year a second statement of the treasurer showed a balance of \$692 92, indicating that more contributions had been received.

The first president, Dr George A Wallace, served until January 1878, when he resigned because of ill health "and the winter." Dr Starr was elected in his place. Dr O E Roe was secretary during the lifetime of the Dispensary.

Although the minutes ended abruptly in October 1877, Dr Starr said in his addenda that the organization existed until January 14, 1879. The Dispensary had done a good work in caring for many of the sick of the city but changing events brought about a lessening need for its services. The City Hospital, now the Rochester General Hospital and St Mary's Hospital had opened free dispensaries. Dr Starr adds, also, that the Womens' Provident Dispensary had opened but Dr Starr wrote his brief historical sketch thirty-five years after the original dispensary had closed and his memory was at fault, for the Womens' Dispensary did not open until 1886.

Besides the opening of hospital dispensaries, there was another reason for closing the Dispensary. The City Council decided that it had no legal right to grant money to the Dispensary and, possibly also lacked the right to give the use of its rooms. Under these conditions, it was voted to close the institution. Thus came to an end a splen-

did work done by a few physicians who gave of their time not only in serving the poor but also in soliciting the funds necessary to carry on the work

The women physicians of Rochester, belonging to the regular school, as stated in the minutes of the Womens' medical society, met on November 23, 1886 at the residence of Dr Mary E Stark to "consider the question of establishing a dispensary for women and children, to be attended by women physicians" At that time, women physicians were not admitted to a position on the staff of any of the hospitals. Indeed, we are told by Peck, that Dr Marion Craig was the first woman appointed on a Rochester hospital staff her appointment as assistant physician at the City Hospital occurring as late as 1898. The object of the new dispensary, as recorded in its minutes, was to provide medical and surgical care for such women and children as should need gratuitous service. Its membership consisted of women physicians and "fifteen other ladies elected by these physicians, not more than three to be chosen from any one religious denomination" Anyone could become an associate member by contributing one dollar or more a year. The active members were taxed one dollar.

Dr Sarah R. Adamson Dolley was elected its first president. Dr Dolley was one of the first of women physicians to be given a medical degree and she became a highly respected practitioner, honored by the entire medical profession. Under her leadership the new Provident Dispensary Association prospered. The Dispensary was open only during the afternoons but in January 1888, it was found necessary to open the clinic two mornings as well. The rooms were on Front Street and at times filled with patients. In 1890, the visits totalled 1,439 but the number of patients was 293. The same year the Association at its May meeting, voted to send thanks to the Common Council for having appointed two women, Dr Harriet Turner and Dr Minerva Palmer on the staff of city physicians.

Besides the dues paid by the members, the Dispensary was supported by private contributions of money and medicines and the city at times appropriated one hundred dollars for medicines. Frequently it was

necessary for the members to impose a small assessment upon themselves to meet a deficit in the treasury. The organization in 1893 was incorporated as the Practitioners Society and its purpose was no longer to support a clinic. Dr Mary Stark said in 1889

The fact of a medical society conducted by women physicians is an innovation in Rochester and our future standing in the profession depends in a degree upon our united and persistent effort to promote the success of this Society. We are the members of a learned profession of which the opposite sex are as the sands of the sea compared with us in numbers. They hold precedence by right of occupation and also by reason of a general prejudice of the public. The hospitals are held by them with few exceptions. The medical societies are under their control, we have been admitted to these after the persistent knocking of the pioneer women of the profession but we are not at home there as in our own circles. We need the general societies to broaden our minds and give us lines of thought but our work and growth should be free where we are without embarrassment or restraint.

The meetings were held at the homes of the members, which since organized as the Practitioners Society consisted of women physicians only. Occasionally, instead of meeting in the city, with the hostess serving a dinner, an entire day was spent at the home of an out-of-town member. The trips were made by train or by "steamer" on the Erie Canal. In 1902, the organization gave a lawn fete and raised one hundred thirty dollars to give a Miss Lai a medical education, so that she might practice medicine in China.

The Society changed its name to the Blackwell Society in 1906, in honor of the first woman physician in the country. The organization still exists but seldom meets. The Dispensary, however, closed its doors and its useful existence in 1894 when the Common Council announced that the Mayor would take over the rooms as a clothing depot for the relief of the poor. In pencil is written a brief note in the minutes of the Society, of a meeting held, no date given, at which time the property of the Dispensary was sold for \$1070 to pay its debts. Thus, a second time we find a clinic for the poor closed when the City refused to give further use of its rooms but each time the refusal came when interest in the project had ebbed.

On March 11, 1907, at a meeting of the

Blackwell Society, a Womens Medical Society of the State of New York was formed, the occasion being a banquet in honor of the seventy-eighth birthday of Dr Sarah Dolley. Its purpose was "to bring women of New York State into communication with each other for their mutual advantage." Dr Dolley was elected president and Dr Elizabeth Blackwell, honorary president. The meetings of the organization were held in Rochester on Dr Dolley's birthday as long as she lived. This State Society of women physicians has continued its activities. Dr Marion Craig Potter of Rochester, daughter, wife, and mother of a physician, has always taken an active part in the State organization and served as its president in 1914.

In the history of the State Society which was given earlier, no attempt was made to bring it up to the present time. Except for mention of a few succeeding dates, the discussion closed with the reunion of the two State Societies in 1906. Likewise, the story of the Monroe County Society ends at an early date. The history of the Rochester Academy of Medicine, on the other hand, comes the present. This is because its union with the Rochester Medical Association is recent and had to be related, in order that its present organization may be understood.

The Rochester Academy of Medicine continues to furnish a meeting place for all medical groups of the vicinity, provides a home and a library for the medical profession and plans scientific gatherings bringing to the city noted men of the profession to address its members. All these medical societies of Monroe County are making history year by year and the story of their various activities for the last two decades is yet to be told.

It is impossible in a few words to tell of the work of the County Society done in the last fifty years and of the important part played in civic affairs. Its Comita Minora has sat in long sessions deliberating upon the business of the Society, recording these sessions in their minute book in a few terse sentences. Working with the Health Bureau of Rochester, the Medical Society of the County of Monroe has had a great share in making this city one of the healthiest and best protected cities in the world. Representatives from other cities and states con-

tinually visit Rochester to study its health measures. Its Child Welfare Stations have served as a model for many communities. Dr George W. Goler, in his unusually long tenure of office as City Health Officer, unhampered by politics, was a pioneer in establishing these Welfare Stations, as well as many other institutions of preventive medicine. The stations were first opened in 1897 in order that pure clean milk might be furnished for infants and that mothers might be taught proper feeding methods. The result was reduction of the former infant mortality rate.

The Certified Milk Commission was another important project of the County Society and Health Bureau. Its first object, the supplying of milk of high standard to sick infants was enlarged until pure milk was available to everyone, with cows tuberculin-tested, blood-tested, and kept clean in body and surroundings and employees working among cows, physically examined every month.

In the treatment of infectious diseases, Rochester has made remarkable progress. During the smallpox epidemic of 1901-02, "Hope Hospital," an old farmhouse between two railroads on the River Boulevard, cared for the many patients and was then destroyed. The next hospital for infectious diseases was the Waring Road Hospital, which, with the smallpox epidemic over, was used in the first movement toward scientific treatment of tuberculosis. The valuable work done by the Tuberculosis Association in its educational campaigns can not be related in these limited pages. Another preventive measure was the crusade against syphilis begun about twenty-five years ago, and about 1915 a campaign was opened for the prevention of diphtheria. Rochester was a pioneer in the use of toxin-antitoxin, as it had been of anti-toxin in 1896. Serum for the treatment of pneumonia was also used here early.

The Iola Sanatorium for Tuberculosis was an early project, as was the Open Air School. The Infants Summer Hospital has been operating since 1893 but now the Convalescent Home for Children, its cares for handicapped children. Another important measure in preventive medicine, was the placing of nurses in the public schools. Medical inspection in the schools began in 1904 when a citizen, Mr. Henry Lomb,

furnished funds to pay the salary of four physicians to examine school children. The City soon realizing the value of such service, assumed the cost, and employed both nurses and physicians. At this time (1936) there are over sixty nurses and twenty part-time physicians in attendance in the public schools. Prenatal clinics were opened in the schools in 1918, and about 1909 the Deafness Prevention Clinic was established through the enthusiasm of Dr Franklin Bock.

The first water supply brought into the city from Hemlock Lake occurred in 1874. There was a long struggle by the Health Bureau to eliminate outside toilets, cesspools, and wells. The first garbage collection ordinance was passed in 1879. Another measure, long advocated by the State Society, the recording of births and deaths, was adopted by this city before many of the other cities. Births have been recorded since 1870 and deaths since 1876. Other matters which frequently occupied the attention of the members of the medical profession and about which many papers were read in the County Medical Society meetings, were the orphanages and the State Hospital. Dr E. H. Howard, for many years superintendent of the latter and an active member and officer of the medical organizations of the community, brought the care of the unfortunates in the State Hospital to the frequent notice of the County Society.

Practically every question pertaining to public health was discussed at length at the County Society meetings and usually resolutions taken or recommendations made. To the lay reader of the old minutes, it is remarkable how the medical men, busy as they were with their patients and their continual reading of medical literature, could have been so altruistic in their attitude toward public welfare. Sanitation and other health measures have been their great interest and the public, feeling secure under the guardianship of the civic health laws, is quite unmindful of the sacrifices of the medical profession that fostered this legislation.

Mention has been omitted of the rise and growth of the excellent hospitals of the city and of the Medical School of the University of Rochester. Theirs is a most interesting story, too lengthy to be included here.

Little has been said regarding any partic-

ular medical man because we have been concerned not with the individual but with organized medicine and its collective action. Mention must be included here however, of a man who stands out in the State records as well as those of local organizations as a great man, Dr Edward Mott Moore. At various times he served as president of the Rochester Medical Society, the County Society, the State Medical Society, the State Medical Association, the Central New York Medical Society, the American Surgical Association, and the American Medical Association. He was active in civic affairs and served for many years as president of the Board of Trustees of the University of Rochester and is called the Father of the Rochester Park System. It was Dr Moore who earnestly endeavored to prevent the split in the State Society, feeling that a few years of careful consideration and patience would adjust the differences existing then. While he stood alone in that struggle, the members on each side heard him with respect and honor. Dr Moore felt keenly the exclusion from the American Medical Association which followed the adoption of the new code and was eager for reconciliation. Negotiations for reunion of the two State Societies and renewed membership in the National body were being contemplated before Dr Moore's death but not consummated until four years after he died in 1902.

The Medical Society of the County of Monroe continues to carry on the great work it has been doing for so many years, seeking not only to protect the medical practitioner and his interests but more than anything else, to protect an unsuspecting public from those who would prey upon it and from the carelessness of thoughtless citizens, and always working through the State Society for the common good of mankind. The County Society has provided from its ranks of leading physicians a number of presidents of the State Society: in 1865, Dr Henry W. Dean, 1873, Dr Edward Mott Moore, 1886, Dr William S. Ely, 1898, Dr John O. Roe, 1912, Dr John F. W. Whitbeck, 1924, Dr Owen E. Jones. And in the Spring of 1937, the State Society will meet in Rochester with Dr Floyd S. Winslow of Rochester, in the presidential chair.

Names of many men who faithfully and excellently served as members and officers of

the County Society, have not been mentioned in this account. A more lengthy history would have much to say of their work. We have avoided as far as possible, tribute to those who are still among us. We are too close to them to clearly distinguish whom should be honored above others. History, like paintings, must be viewed from a distance, if one would see the whole picture.

In closing, may we say as we did in the beginning of this record, that these historical events have been related by a layman, perhaps not fully understanding all that transpired in these bygone medical meetings but appreciating to the utmost, the earnest efforts of these medical men who accomplished great deeds through organized medicine, so that there may be better and happier living for all. Having quoted so

freely in these pages from former presidents of the State Society, men who have served and passed on, we close with another quotation, this one from the annual address of Dr Henry W Dean of Rochester, president of the State Society in 1866. Dr Dean closed his address with these words, "Let medicine continue her unwearied efforts in the realm of physical observation and experiment, let her widen perpetually her range of mechanical and scientific resources, and let her with this, blend all proper, judicious appeals to that intelligent, immortal nature with which she has to deal, then she will fulfill her mission in all its unspeakable grandeur."

NOTE The writer wishes to express thanks to Dr Norris G Orchard of Rochester for editing this paper

Medical Society of the State of New York Presidents

1807	William McClelland	Albany	1874	George J Fisher	Sing Sing
1808-10	Nicholas Romayne	New York	1875	Thomas F Rochester	Buffalo

THE END OF A COUNTY SOCIETY

The Wyoming State Medical Society has rescinded the charter of one of its county societies, because, as officially explained, for years the county society "has been a hot-bed of contention and has not been a factor in elevating public opinion of the local

medical profession The absolute refusal of that Society to comply with an order of the Council, sitting as the highest court in our State Society, was the cause of rescinding its charter, thus ending its life"

Medical News

Secretaries of County and local Medical Societies are requested to send the programs of coming meetings to this department one month in advance, for the information of members who may be interested

Chautauqua County

THIRTY-FIVE MEMBERS were present at the meeting of the Jamestown Medical Society held Nov 19 at Hotel Jamestown. Dr George M Shearer, president, presided at the session.

Dr Carl H Lenhart, professor of surgery at Western Reserve University, gave a paper on "Surgical Diagnosis." Dr Milton J Johnson, Dr George W Cottis, Dr Harold A Blaisdell, Dr Hammerstrom and others present took part in the discussion. A smorgasbord was served.

At the next meeting, on January 28, Dr Herbert A. Smith, professor of surgery at the University of Buffalo, will speak on "Discussions and Conclusions of Gastric Surgery." Dr Cottis will lead the discussion.

Chemung County

A CENTURY OF MEDICINE in Chemung County was reviewed on Nov 21 by the Chemung County Medical Society at its centennial celebration at the Mark Twain Hotel in Elmira.

More than one hundred physicians and dentists from six counties in southern New York and northern Pennsylvania heard Dr Floyd S Winslow of Rochester, president of the State Medical Society, praise the county society's illustrious history and its present strength and service.

After the commemorative dinner Doctor Winslow opened the speaking program with a brief resume of social problems which the medical profession must face.

Review of medicine in the county for the past 100 years was made by Dr Arthur W Booth in a paper, "A Century of Medicine in Chemung County."

"Medicine in the '90's," a paper by Dr Ross G Loop, reviewed the practices and medical beliefs just before the turn of the century when he entered the profession.

Dr Anna Stuart, introduced as "one of the most lovable characters medicine ever produced," spoke on women physicians in Chemung County.

Elmira has always been a haven for women physicians, she said, chiefly because of the respect the city bore for Mrs Rachel Gleason.

Dr Reeve B Howland described instru-

ments used by physicians at the turn of the century.

The centennial program closed with a playlet, "The Doctor's Dream" which contrasted the medical knowledge of 1840 with that of today. The skit was written by Doctor Booth and directed by John Colgan, dramatic coach at Elmira Free Academy.

Those in the cast were Doctors Wytenbach, Charles Stevens, Joseph S Lewis, LaRue Colegrove, Lawrence L Hobler and R Scott Howland.

Chenango County

THE 132d ANNUAL MEETING of the Chenango County Medical Society was held on Dec 8. After a luncheon with the Norwich Rotary Club at the Chenango Hotel, the society held its business session at the Norwich Hotel and listened to a paper on diabetes mellitus by Dr M S Bloom, of Binghamton. The discussion was opened by Dr Wayland Mason, of Norwich.

Erie County

DR. THEODORE MILLER LEONARD, who had practiced medicine in Buffalo thirty-five years, died of pneumonia on Nov 19 at the age of fifty-nine. He taught medicine at the University of Buffalo for many years.

Franklin County

URGING THE ESTABLISHMENT of county laboratories to facilitate treatment of disease, a delegation of physicians of the Franklin County Medical Society from Saranac Lake and Malone appeared on Dec 1 before the Board of Supervisors.

The project was brought forward through a resolution adopted at the last meeting of the society.

The plan, as outlined by Dr Charles Trembley of Saranac Lake, would provide for a main laboratory at Saranac Lake with branches in Malone and Tupper Lake. The state would provide \$2,500 for equipment of each of these. The county would have to contribute about \$4,500 for maintenance to which the state would add an equal amount, creating a \$9,000 maintenance fund.

Dr Trembley said that the appropriation of \$4,500 might be cut down to some extent

through payment for the services of the laboratory by those who were able

Dr Trembley, Dr Daisy Van Dyke, Malone village health officer, and Dr John E White of Malone presented arguments in favor of the laboratory plan

They pointed out that it would be a factor often in saving lives of patients in cases where an immediate diagnosis and serum treatment was imperative. In the case of pneumonia there exist several different types, each requiring a different serum. By "typing" the case immediately, prompt treatment might bring relief and save the life of the patient.

Under the present system it is necessary to send cultures to Albany with the result that there is considerable delay

The delegation was assured by Chairman Arthur D Erwin that careful attention would be given the proposal by the board

Fulton County

DR. PHILLIP BARTON of Amsterdam was the speaker at the regular monthly meeting of the Medical Society of Fulton County held on Nov 19 at Hotel Johnstown in Gloversville. Dr Barton's subject was "Bronchoscopy in General Medicine"

There were about twenty members in attendance

Genesee County

A SPECIAL COMMITTEE of the Genesee County Medical Society is considering organizing a ladies' auxiliary

The committee will investigate and report at the next meeting. Officers elected at the last meeting are Dr Elmer E Owen, president, Dr W C Swasey, vice president, and Dr Peter J DiNatale, secretary-treasurer

Jefferson County

DR. WILLIAM J KELLOW, seventy-seven, of Watertown, who retired in 1929 after an active medical practice of forty-seven years, of which thirty-eight years were spent in Watertown, died on Nov 23 at St. Petersburg, Fla., where he and his wife were spending the winter

Dr Kellow was born Sept 15, 1859, at Taron, Burke county, Ont., near Toronto. He studied at Toronto Medical college, Victoria college at Coburg, and McGill university at Montreal

He received his diploma and degree of doctor of medicine from Victoria college on May 16, 1882

From 1883 to 1890 he practiced in Harrisville. The only doctor in the Harrisville area in those days, he had an extensive

territory to cover as the nearest doctors were at Gouverneur on the north, Natural Bridge to the west, and Croghan to the south. There were lumber camps in the deep forests, isolated farm homes and a wide area of unbroken wilderness. The automobile had not been heard of and the young physician had to cover this wide territory by horse and rig. The population was scattered among lumber hamlets

On winter nights he was compelled to travel with horse and sleigh over unbroken roads to reach his patients and many times he tried to reach some farm or camp miles away at a late hour of the night. It was not unusual for him to have to use six horses in a day and there were times when Dr Kellow had to tramp ten miles through the snow in the night to reach some patient's bedside, the trips being impossible with horse and sleigh

Continual driving about the rough country roads finally impaired his health and he was advised by another physician to locate in some center where he could do more walking and less riding

After eight years in the forest territory, Dr Kellow went to New York for six months, spending the time in the various hospitals and the Post-Graduate Medical school and hospital, and then he came to Watertown to continue his practice

Kings County

THE MATERNITY CENTER DIVISION of the Brooklyn V N A has adopted a five-point program in the further advancement this year of its effort to safeguard the health of mothers and new-born babies and to assist in the movement to reduce the maternity and infant mortality rate in Brooklyn. Mrs Albert W Meisel, chairman of the division, has announced

The five-point program follows

1 To assist the Committee on Maternal Welfare of the Medical Society of the County of Kings in the study of all maternal deaths as they occur in Brooklyn.

2 To arrange groups in Brooklyn to be addressed by physicians on "What Constitutes Adequate Maternal Care?"

3 To conduct classes giving instruction in prenatal, infant, and postnatal care to expectant mothers

4 To compile and maintain a current resource file on all maternity facilities in Brooklyn

5 To visit expectant mothers in their homes and under the direction of a physician teach hygiene, observe adverse symptoms and help plan for the expected baby

Livingston County

DR WILLIAM H KOBER of Lima was elected president of the Livingston County Medical Society at its annual meeting at Avon

Other officers are Dr Charles Smarzo vice-president, Dr Robert Lewis, secretary and treasurer

Dr J M Burt was named delegate to the state convention and Dr F V Foster alternate The speaker of the evening was Dr Floyd Winslow

Monroe County

URGENT RECOMMENDATION that every state pass a law requiring persons considering marriage to be blood tested at approved laboratories was made in Rochester by Dr Thomas Parran Jr, surgeon general of the United States on Dec 2

Doctor Parran made the recommendation in a plea for public co-operation on the subject "Why Not Stamp Out Syphilis?" before several hundred Rochesterians in the Chamber of Commerce

"Rochester, a pioneer in the work, ranks highest of any city in the country in health," he said, paying tribute to the work of Dr Joseph Roby, deputy health officer

Rochester can point to its record with pride and thanks for the co-operation of an efficient Health Bureau, the Chamber of Commerce, the Medical Society of Monroe County, and the County Tuberculosis and Health Association, he declared

DR RALPH HERMON MAJOR, professor of internal medicine at the University of Kansas, lectured on Dec 3 in the Rochester Academy of Medicine on Lipoid nephrosis

He is the author of several medical books and during the World War was a captain in the Medical Corps

THESE OFFICERS were elected at the 116th annual meeting of the Medical Society of the County of Monroe on Dec 15

President, Dr E G Whipple, Vice-President, Dr Leo Simpson, Treasurer, Dr J J Rooney, Secretary, Dr W A MacVay Board of Censors Dr Floyd S Winslow, Dr Warren Wooden, Dr J M Flynn, Dr Joseph Henry, Dr B J Slater

Delegates to State Society—for two years Dr C V Costello and Dr E T Wentworth Alternates—Dr Frank Colgan and Dr E G Whipple Members of Milk Commission—for three years Dr Lloyd Allen and Dr Howard Rowley

New York County

CO-OPERATION BETWEEN DOCTORS and den-

tists in the early diagnosis of syphilis and cancer was discussed by the joint committee of the Organized Medical and Dental Professions of the City of New York at its sixth annual convention in the Hotel Pennsylvania on Dec 7

Dentists have a social responsibility in detecting symptoms of cancer and syphilis in their patients according to papers presented at the meeting The consensus was that the average dentist had enough medical knowledge to be able to make a tentative diagnosis of either disease

Dr Samuel Feldman, attending dermatologist at Morrisania Hospital and chief of clinic at the Bronx Hospital, reported that swellings and ulcerations in the mouth often were the first symptoms of syphilis or cancer He warned that poorly fitting false teeth might cause irritation which might produce a cancerous condition

"Continued irritation of the mucus membrane of the tongue or the lining of the mouth predisposes to cancer," he said

In New York City two and one-half per cent of the population had syphilis infection, he said, while in the whole nation the infection rate was five per cent Because of the lack of clinics the syphilis rate in country regions usually was double that of the cities, he said

"Mouth lesions of this disease come as the result of drinking from a glass or cup that has been used by a person who has this disease in active form," he added

Dr Hayes E Martin, attending surgeon at Memorial Hospital, called on dentists to be alert constantly for early symptoms of cancer of the lip and mouth cavity

"In a considerable number of cases in our clinic we find that credit for the first tentative diagnosis of cancer should be given to the family dentist," he said "A close co-operation between the medical and dental profession is of great importance to public health Many patients are indebted to their dentists for the first recognition of cancer of the mouth while the disease was in the early and curable stage"

DR WARREN STONE BICKHAM, seventy five, surgeon and author of surgical text books, died at his home on Dec 1

Dr Bickham, a native of Louisiana, formerly was an instructor of surgery at New York Post-Graduate Medical School and Hospital and Polyclinic Medical School

He was a fellow of the New York Academy of Medicine and the American College of Surgeons and a member of the Yale Club and the Authors' Club of London

Onondaga County

DR. J. R. WISEMAN was elected president of the Onondaga County Medical Society on Dec. 1. Other officers elected were Dr. O. W. H. Mitchell, vice president, Dr. L. E. Sutton, secretary, and Dr. J. F. Cahill, treasurer.

Ontario County

DR. ALFRED M. MEAD, senior member of the attending staff of Thompson Memorial Hospital in Canandaigua, and a member of the Board of Directors, was honor guest at a dinner given by the hospital on Nov. 21 in the Nurses' Home. It was Dr. Mead's eightieth birthday anniversary. Despite his advanced years, he is in good health, attends to his practice, and as a member of the attending staff visits the hospital daily.

Dr. Mead graduated from Buffalo Medical College in 1880 and opened offices for general practice soon after, completing fifty-six years of active service last March. He is active in community life as well as in his profession and has served in various public offices, including county coroner, trustee and health officer of Victor village and president of the Board of Education of Victor High School. Among medical organizations, he is a member of the Ontario County Medical Society, which six years ago honored completion of his half-century of membership with a complimentary dinner and other fitting tributes.

Otsego County

THE ANNUAL MEETING of the Otsego County Medical Society was held at Cooper Inn, Cooperstown, on December 9, at which time the following officers for 1937 were elected:

President, Dr. Francis F. Harrison, Vice-President, Dr. Norman W. Getman, Treasurer, Dr. Frederick E. Bolt, Secretary, Dr. Floyd J. Atwell, Censor, Dr. Earl C. Winsor, Delegate for the Society, Dr. Floyd J. Atwell, Alternate Delegate, Dr. Edwin P. Hall, Workmen's Compensation Committee, five-year term, Dr. Monroe McIver, and a member to the Workmen's Compensation Committee to fill the vacancy caused by the death of Dr. Mills, Dr. Alexander F. Carson. Reported by F. J. Atwell, M.D., Secretary.

Putnam County

INTERESTING MEETINGS have been held during recent months by the Putnam County Medical Society, as reported by Dr. John T. Jenkin, of Lake Mahopac, Secretary.

The meetings were held at the Carmel Country Club, at Carmel. The following speakers have addressed the Society:

October 9 Dr. Raymond H. Goodale, Associate Professor of Clinical Pathology at Boston University and former Professor of Pathology at American University, Beirut, Syria, spoke upon "Pathologic Physiology of the Liver."

November 4 Dr. William J. Vogeler, Physician to St. John's Riverside Hospital, Yonkers, New York, spoke upon "Coronary Thrombosis and its Electrocardiographic Findings."

December 2 Dr. James E. Sadlier, Surgeon to St. Francis Hospital, Poughkeepsie, spoke upon "Surgery of the Large Intestine."

Queens County

DR. EVAN W. McLAVE attending physician at St. John's and Bellevue Hospitals and chief of medical clinic at New York Medical College, Manhattan, spoke on the clinical manifestations and treatment of lobar pneumonia on Dec. 4 at the Queens County Medical Society Building.

The program was held under the auspices of the committee on graduate education of the Queens County Medical Society.

Rockland County

THE MEDICAL SOCIETY of the County of Rockland elected the following officers for 1937 at the annual meeting Dec. 2, at Nyack, as reported by Dr. Ryan, Secretary:

President, Dr. George W. Unsworth, Vice-President, Dr. Frederick A. Schroeder, Secretary, Dr. William J. Ryan, Treasurer, Dr. Dean Miltimore.

The chairmen of the five standing committees are:

Membership, Dr. John W. Sansom, Legislative, Dr. John C. Dingman, Public Health and Public Relations, Dr. George M. Richards, Medical Economics, Dr. Harold S. Heller, Physical Therapy, Dr. Leo G. Weishaar.

STATE SENATOR RAE L. EGBERT addressed the members in a succession of humorous stories and anecdotes, but in closing said that he planned to cooperate with the physicians in his coming term as he had in his last. Dr. William C. Buntin of St. George, S. I., was introduced and as head of the First District Branch invited the physicians to attend the semi-annual clinical sessions.

Dr. Harrison S. Martland, of Newark,

Livingston County

DR. WILLIAM H KOBER of Lima was elected president of the Livingston County Medical Society at its annual meeting at Avon

Other officers are Dr Charles Smarzo vice-president, Dr Robert Lewis, secretary and treasurer

Dr J M Burt was named delegate to the state convention and Dr F V Foster alternate The speaker of the evening was Dr Floyd Winslow

Monroe County

Medicolegal

LORENZ J. BROSNAN, Esq.

Counsel. Medical Society of the State of New York

Privileged Communications—Dentists

Although there is a considerable amount of precedent throughout the country, both by decided cases, and by statutory enactment upon the subject of confidential communications as affects physicians, there seems to be relatively little authority upon the same subject as it effects dentists. However, in a recently decided case,* the Courts of one of the Southern States had occasion to pass upon the question of whether the rule governing disclosure of professional information by physicians and surgeons included dentists as well.

The case was one instituted against a railway company for damages for an assault claimed to have been committed by a trainmaster. It appeared that the plaintiff was engaged in assisting certain railway porters in transferring baggage at a junction. As he was coming off one of the trains he claimed that the trainmaster had kicked him and told him to stay off the train, and that as he turned to see the cause of the kick, he had been struck in the mouth. The defendant's witnesses testified that the trainmaster had struck the man only after first remonstrating with him against damaging railway property, and to prevent an intended blow from the plaintiff. The plaintiff claimed his injuries had included a broken tooth and a condition of inflammation and pus about the said tooth.

Upon the trial of the action the plaintiff testified that he had consulted a dentist and received treatment, but when the defendant undertook to introduce his testimony in evidence an objection was made by the plaintiff to such testimony as confidential in nature. The statutory provision under which the objection to the dentist's testimony was taken was as follows:

Communications privileged — All communications made to a physician or surgeon by a patient under his charge or by one seeking professional advice, are hereby declared to be privileged, and such physician or surgeon shall not be required to disclose the same in any

legal proceeding, except at the instance of the patient.

The Court after a colloquy with counsel in which he elicited the opinion of counsel that "a dentist is a physician" sustained the objection and ruled that the dentist should not testify. The trial resulted in a judgment in favor of the plaintiff.

Upon an appeal, the Appellate Court ruled that the Trial Judge had erroneously ruled upon the question, but affirmed the judgment since it did not appear that if the dentist had testified fully the outcome of the case would have been different.

In its opinion the Court said:

The purpose of this statute was to protect physicians and surgeons from having to testify as to communications made to them in their professional capacity, and to protect patients from having to disclose statements made to physicians. The statute must be limited to its language and clear purpose. It has the effect of preventing facts from being disclosed which would often be material to the administration of justice, and it should not be extended by construction.

In this State the statute regulating the disclosure of professional information is Section 352 of the Civil Practice Act which provides in part as follows:

Physicians and nurses not to disclose professional information. A person duly authorized to practice physic or surgery, or a professional or registered nurse, shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity and which was necessary to enable him to act in that capacity, ***

Some twenty years ago in a case* which came before the Appellate Term of the Supreme Court it was held that said section had no applicability to dentists. In the course of the opinion in that case the Court said:

Strictly speaking a dentist might be included within the description relating to those who practice "surgery," but, as the term "surgery" is employed in the Statute, it does not include one engaged in the practice of dentistry. ***

In early days in England the province of

*Gulf, Mobile & N R Co v Willis, 157 So 899

*Howe v Regensburg, 75 Misc. 132

N J, chief medical examiner of Essex County, New Jersey, was introduced as the principal speaker, and illustrated his talk, "Some Interesting Cases from the Medical Examiner's Office" with lantern slides, showing various pictures of bodies found in notable murder and suicide cases in the files of the Essex County police.

Prior to the talk, Dr S R Monteith gave several solos and led the group in singing.

THE WOMAN'S AUXILIARY to the Rockland County Medical Society was organized at a meeting held at Summit Park Recreation Hall on Wednesday afternoon, November 4.

The officers of the organization are President, Mrs S W S Toms, president-elect, Mrs A N Selman, first vice-president, Mrs W J Ryan, second vice-president, Mrs F A Glass, recording secretary, Mrs E H Kline, corresponding secretary, Mrs J Pomerantz, treasurer, Mrs L G Weishaar, historian, Mrs George M Richards.

Schenectady County

DR ARTHUR Q PENTA, director of the bronchoscopic clinic in the Schenectady City hospital, has been awarded a membership in the National Academy of Medicine in Brazil. The award is in recognition of Dr Penta's outstanding work in the field of bronchial asthma and his contribution to South American medicine in relationship to oral infection to pulmonary suppuration. The honor is limited to few foreign physicians.

Dr Penta plans to leave in July for Rio de Janeiro to be present at a special meeting of the National Academy of Medicine, when he will receive the official medalion of the academy.

Seneca County

ESTABLISHMENT OF A COUNTY-OWNED laboratory, to be used by the physicians of Seneca County as a helpful factor in the prompt and efficient diagnosis of disease was urged on Dec. 3 by four representatives of the Seneca County Medical Society, who appeared before the Seneca County Board of Supervisors.

The representatives of the medical group, each of whom spoke briefly in favor of creating a laboratory were Drs W R Holmes and Edward M Wellberry of Waterloo, and Drs Frederick W Lester and Robert F Gibbs of Seneca Falls.

Dr George B Adams, director of the Cayuga County laboratory in Auburn, told the county governing board about the man-

ner of establishing a county-owned laboratory, its many advantages and its cost.

Doctor Adams estimated the cost of establishing a laboratory in Seneca County at between \$5,000 and \$6,000.

Suffolk County

THE SUFFOLK COUNTY Medical Society will build and present to the Suffolk Boy Scout Council a small infirmary hut for use at Camp Baiting Hollow, according to Dr Grover A Silliman of Sayville. The infirmary, to be ready for use next Summer, will be for the occasional camper who needs special attention.

Tioga County

DR I N PETERSON, SECRETARY, reports that the annual meeting of the Medical Society of the County of Tioga was held at Owego on Dec 1. There were thirty-two members and guests present.

Following a turkey dinner, Dr L D Hyde called the meeting to order. After other business the following officers were elected for 1937: President, Dr L D Hyde, Vice-President, Dr C S Johnson, Secretary-Treasurer, Dr I N Peterson, Censors, Dr F A Carpenter, Dr E E Beck, Dr F S Spencer.

The Chairman of the Program Committee, Dr Osborne, introduced Dr John Deegan of the Herman Biggs Memorial Hospital at Ithaca who spoke on the scope and plan of the work being started at this institution. Dr Osborne then introduced Dr Ethan Flagg Butler of the same hospital who gave the society a clear and comprehensive discussion of "The Surgical Treatment of Pulmonary Tuberculosis." The lecture was discussed at some length by the members present.

Warren County

AT A MEETING of the Glens Falls Academy of Medicine on Nov 27 an address on "Hyperparathyroidism" was delivered by Dr Fuller Albright of Boston, Mass. Dr Albright is associate professor of medicine at Harvard Medical School.

MEMBERS OF THE GLENS FALLS Medical staff met on Dec 1 in Glens Falls Hospital. Dr J Leonard Byrnes of Hudson Falls suggested the need of complete medical and surgical equipment in the ambulance. The surgical committee was appointed to look into the matter. Dr Dwight M Sawyer presented a paper on the death of two patients recently in the hospital and their cases were discussed.

Across the Desk

Cutting "Siamese Twins" Apart

A RELATIVE IS SOMETIMES SPOKEN of as a "connection," but when the connection is actual, then the relatives are candidates for circus sideshows and museums of freaks, parading as "Siamese twins." It was none other than the immortal and redoubtable P T Barnum who started the exhibition of these linked ones when he imported "Chang and Eng" from Siam and exhibited them to the gaping gaze of the gullible. Such freaks of nature are also of interest to the medical profession, especially when the surgeon is called in to separate them, as sometimes happens.

It is of course almost unthinkable that one conjoined twin should die and the other survive. In some cases, like Chang and Eng, the twins have a joint circulatory system, and any infection invading one inevitably affects the other too. The linked Filipino brothers who died at the York Hospital in New York City a few weeks ago had independent circulatory systems, and when Lucio Godino died of rheumatic fever on Nov. 24, the surgeons took a long chance and severed the tissue that held Simplicio to him. The link, according to the information given out to the press, was a mass of muscular tissue twenty-four inches in circumference, at the base of the spine. "Organically," we are informed, "they were separate except for the fact that the lower end of Simplicio's large intestine passed through the connecting stalk into Lucio's body where the two alimentary systems merged into one. After the separation, an operation was necessary to reconstruct plastically the outlet of Simplicio's colon." At first Simplicio seemed to be recuperating from the operation, but on Dec. 4 spinal meningitis developed, and he died the next evening.

Handy Military Formation

The Godino twins were born in the island of Samar, in the Philippines, twenty-eight years ago, and when they were twenty-one they married Natividad and Victorina Matos, sisters. When they applied for U S citizenship, we read, they were told that in order to be eligible for it, they

would first have to serve three years in the Philippine Army! As they faced in opposite directions when walking, they would at least always be ready for advance or retreat, and the command "about face" would require no exertion at all.

The condition in Siamese twins is considered to be caused by a joining of two fertilized life cells at the moment of conception. Sometimes the twins are joined at the hip, sometimes at the skull or stomach. Those that have survived childhood have been joined at the hip. In addition, in most cases, to sharing one circulatory system twins have been known that shared one stomach, one alimentary canal, and even one heart. These types usually do not survive birth and more often die in the fetal state.

Two Successful Separations

Is it possible to separate conjoined twins successfully in infancy? By a strange coincidence, there came to this desk at the time of the Godino operation two medical journals, one from Minnesota, over 1,000 miles to the west, the other from London, 3,000 miles to the east, both telling of successful operations of this kind. A correspondent of the London journal writes that the last previous successful surgical feat of this sort was performed by Dr. Fatius of Basle in 1689.

The rarity of this surgical intervention, then, may warrant some description from the pens of the men who did it. We may give the American surgeon first place, perhaps, because his un-Siamesed twins lived for nine years, healthy and hearty, and apparently normal little girls ready for three meals a day and a few good extra snacks in between. They were Zelda and Elda Alsleben. Elda died last March of pneumonia, which may have had no relation to the operation performed years before by the surgeon. He is Dr. Hillard H. Holm, of Glencoe, Minn., and the story appears in *Minnesota Medicine*, for November, as a report of his paper read at the annual meeting of the Southern Minnesota Medical Association in August. The paper was awarded a medal as the most interesting

the dentist was not recognized, except as it fell within the scope of the functions of the "barber-surgeon," whose multitudinous duties often included those not only of the barber and surgeon, but the physician and dentist as well.

Within quite recent times it was customary for barbers and blacksmiths to extract teeth. Formerly the work of filling and plating teeth was frequently performed by the jeweler. A process of integration and differentiation has taken place, and the separate and distinct profession of dentistry has come into existence. That this specialization has resulted beneficially to the community and that dentistry has now become a highly developed science, requiring of its practitioners advanced knowledge and skill, is doubtless true, but this fact does not militate against the construction of section 834 of the Code of Civil Procedure, excluding a dentist from the operation of its provisions. There is clear evidence in the statutes of this State of a legislative intent to regard the two professions of medicine and dentistry as separate and distinct.

The Court also referred to an earlier case* decided in one of the mid-western States in which a similar ruling had been made.

In that case the Court said "The purpose of the act is to be considered in determining whether the dentist was intended to be included within its terms. Certainly the terms dentist and surgeon are not interchangeable, and if a dentist is to be held a surgeon, within the meaning of this act, it must be because his business as a dentist is a branch of surgery. It is apparent that the act relates to general practitioners, and to those whose business as a whole comes within the definition of physician or surgeon. A dentist is one whose profession it is to clean and extract teeth, repair them when diseased and replace them, when necessary, by artificial ones."

While the definition of a dentist here given seems to us to be too restricted, in view of the progress as a science which dentistry has recently made, we are of the opinion that the decision in the case quoted was correct and that it properly interpreted the meaning which the Legislature intended should be given to that statute.

Alleged Illegal Commitment

Two physicians who were qualified examiners in lunacy were called upon by a City Judge to come to his office for the

*People v DeFrance, 1104 Mich 563

purpose of examining a person who was charged with being incompetent and in need of care in an institution for the insane. The two doctors jointly made a physical and mental examination of the person in question and found him to be a middle aged man in good health. After a lengthy psychological examination both of the doctors concluded that he was suffering from ideas of persecution and needed institutional care.

The man's wife executed a petition for his commitment and the two doctors as qualified examiners in lunacy executed the usual certificate in lunacy.

Later a charge was made by the alleged incompetent that the papers were defective since he claimed that one of the examiners was distantly related to him and another examination was made in which a third doctor participated, and again the papers were completed and upon said papers he was committed by Court order to a State Hospital.

After he remained in that institution for some period of time an application was made on behalf of the alleged incompetent to obtain his release by habeas corpus proceedings. He obtained a jury trial which resulted in his release. Upon the said trial none of the doctors who had executed the certificates of lunacy were called to testify and as a matter of fact they received no notice of the proceedings.

After some time had elapsed the alleged incompetent instituted an action against the three doctors, charging them with having joined in a conspiracy to deprive him of his liberty and having executed commitment papers knowing that he was in fact in all respects sane. He made an attempt to charge that the doctors were in collusion with a well-known wealthy man in the community acting with the purpose of attempting to railroad the plaintiff into an asylum at the instance of this wealthy man.

Before the case could be reached for trial one of the defendant doctors died and the action consequently abated as to him.

The case came on for trial as a jury case and at the conclusion of the testimony put in on behalf of the plaintiff the action was dismissed. The Court in so deciding thereby exonerated the defendants of all charges that they had acted improperly in connection with the case being apparently in part at least influenced by the manner in which the plaintiff himself testified while on the stand.

According to a doctor, white marks on a man's finger-nails are a sign that he needs to be more careful about his nerves. Black

marks on his thumb-nail are a sign that he should be more careful with his hammering.
—Punch (London)

X-ray plates were also made. From this examination it could be determined that each child had a separate gastrointestinal tract and that there was no union of either stomach to stomach, or intestine to intestine

How it was Done

As Siamese twins could not possibly go through life joined in such a manner and since they had separate organs, it was decided to separate them. Consequently on March 1, when they were about seven weeks old, operation was undertaken

The infants were placed on their sides, being the right side of one baby and the left side of the other. A light ether anesthetic was given. With the scalpel an encircling incision was made through the skin around the pouch, midway between the infants and splitting the umbilicus below. Entrance was gained into the pouch through the upper, or nearest, portion. In order to get into the pouch a thin fascia, a small muscular layer and finally the peritoneum were incised. This was done with extreme care. Moist packs were then inserted to hold back the intestines and the incision carried completely around the pouch through the fascia, muscle and peritoneum up to the ensiform cartilage, which was continuous from one infant to the other. This was cut with a straight scissors. The falsiform ligaments of the livers of the infants being also united, clamps were applied and they were severed and tied off with plain catgut No 2. The infants were thus completely separated.

Following the separation one of the infants was noticed to become very pale and to stop breathing. The anesthetic was stopped and hypodermic of adrenalin and camphorated oil, which had been held in readiness, soon brought the infant back to normal condition. It was now necessary to sew up the openings into the abdomens where the pouch had been. This was a difficult procedure and had to be done quickly. One of the infants was tended by a nurse, the anesthetic being stopped on that one. On the other infant the peritoneal covering was then picked up and dissected back. This was sutured in a continuous running locked suture of plain catgut No 2. Four stay sutures were then placed through the skin, subcutaneous fat, rectifascia and muscle, down to the peritoneum. These were left untied. The rectifascia was then sutured together with No 2, forty-day chromic catgut in a running locked suture. It was somewhat difficult to draw this together in the midportion, due to the fact that we were making a straight wound out of a round opening. The skin was then sutured with plain catgut No 2 in a running, continuous suture. The stay sutures were then tied and dressings applied. The other infant was then given a

small amount of anesthetic and the suturing of the pouch was done in a like manner. Each infant had a small umbilicus at the lower end of the incision after the operation had been completed.

After the infants had been put to bed they were both given hypodermoclysis of normal saline into each leg, approximately 150 c.c. being given to each baby. Twelve hours post-operative the mother nursed each baby, and they took the breast well. She continued to

Fig 2 Nigeria twins showing site and degree of junction

nurse each infant every four hours during their stay in the hospital. Each infant occasionally had crying spells, which was undoubtedly due to some pain, but otherwise they had a remarkable convalescence, the incisions being completely healed in ten days, at which time the stay sutures were removed.

The infants were seen every month after the operation for an entire year, during which time they were nursed by the mother. At the end of five months solid food such as cereals and mashed vegetables were added to their diet. After the first year they were seen at frequent intervals and were weighed and carefully watched.

Two Little Maids of Nigeria

Now we go from Minnesota to Nigeria, Africa. The African twins are a little over one year old and have been leading separate lives for six months. They are now "in every way normal and vigorous infants,"

one at the meeting, which "sounds reasonable," as they say

The Minnesota twins were born in a raging blizzard on January 8, 1927, in a farm home some fifteen miles from town, recalls Dr. Holm. He proceeds

The mother was a primipara. Labor had gone along normally for about eighteen hours. Previous examination of the abdomen had revealed that undoubtedly twins were to be born, as two separate fetal heart tones could be

infants were then rotated so that they were face to face, which apparently untwisted the pouch connecting them. It was a strange sight to behold, and I must admit that Dame Fortune was with me because if the two heads had presented at the same time, instead of a head and a foot, the infants could not have been born without a cesarean section.

Both infants were normal in every way except for their being attached together. Their rectal temperatures were each 99.8 degrees, and pulses 125. Each child's heart and lungs were

Fig 1 (Left) Siamese twins born January 8, 1927 (Minnesota) Six weeks after birth (Right) Two weeks following operation

heard, although the parts could not be definitely determined. At the end of nineteen hours of labor the head of one child was delivered normally, the occiput anterior. On attempting to deliver the shoulders they were found to remain stationary and could not be delivered. It was a baffling situation. After studying the situation carefully I passed my right hand up into the vagina, up alongside the abdomen of the child to be born, and felt two feet. These I grasped and exerting traction on them, at the same time pulled with my left hand on the shoulder of the child being born. Immediately the shoulders slipped out, and along came the feet of the second child as well as the buttocks and the abdomen. The buttocks and feet of the first child were then delivered free of the vagina and a connection was noticed between the twins. The head of the second child was then delivered, as in a breech extraction. One umbilical cord was present, attached at the under surface of the union of the two babies.

Dame Fortune Was With Him

After the cord had been clamped and tied and dressed it was noticed that the pouch connecting the two children was twisted. The

normal in every way. Their abdomens were joined together over an area approximately four inches in diameter and thirteen inches in circumference. The ensiform cartilages were continuous from one child to the other. One umbilicus was present and entered the lower portion of the attachment. Liver and spleen were not palpable in either child.

Blood examination on February 28 showed a hemoglobin of 76 and 78 per cent and red cells of 4,100,000 and 4,300,000 respectively.

X-ray examination was made and plates were taken. One of the children was given a mixture of barium with mother's milk, which it took from the nursing bottle. This was followed up by means of the fluoroscope and it was found that the barium and milk mixture entered into a normal stomach, from which it quickly passed out into the small intestine. The child was spanked and caused to cry, and under the fluoroscope it was seen that the small intestine would push over into the abdominal cavity of the other infant through the pouch, and when the baby stopped its crying the intestine would go back into the proper abdomen. A similar procedure was carried out with the other infant and showed the same condition.

Books

Books for review should be sent directly to the Book Review Department at 1313 Bedford Avenue Brooklyn, N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.*

Delafield & Prudden's Text Book of Pathology Revised by Francis C Wood, M D. Sixteenth edition. Octavo of 1406 pages, illustrated. Baltimore, William Wood & Company 1936. Cloth, \$10.00.

The sixteenth edition of this extremely popular text-book of pathology, has had the welcome received by its predecessors renewed.

To those who object that the book is not sufficiently modern, in that it fails to include a description of some of the more recent advances in pathologic knowledge, let this excerpt from Dr Francis Carter Wood's introduction to this edition be an answer "People still have the same lesions that they had when Delafield and Prudden wrote the first edition, even though the names may have changed, and it is important for the student to learn these lessons."

This book will probably, as did the previous editions, retain its standing as a reference work for the student of pathology, who will derive from its use the satisfaction that his reading, though it may not be of the most modern work, will certainly be authoritative.

EMIL F KOCH

Oral Diagnosis and Treatment Planning A Text for the Dental Student, A Reference Book for the Practitioner and Medical Student. By Kurt H Thoma, D M D. Octavo of 379 pages, illustrated. Philadelphia, W B Saunders Company, 1936. Cloth, \$6.00.

This book lives up to its title in every respect. There is a page devoted to instructions in its use, which makes for ease of consultation, when used as a reference by the practitioner or student. The work is decidedly original, well planned and profusely illustrated.

The author presents in logical sequence the theory of diagnosis and treatment, consisting of examination, diagnosis, tentative, differential, final diagnosis and post-operative prognosis forecast, treatment and treatment planning. The section devoted to methods of examination sets forth technique

for history taking and recording, both for general physical examination, laboratory methods and special examination for dental and oral diseases, concluding with a chapter devoted to roentgen examination of the teeth and jaws. The latter chapter is invaluable to the general medical practitioner, who is so often consulted for an opinion on dental radiographs.

Part III covers clinical diagnosis of dental and oral disease, malformations of the head and jaws, maldevelopment and an excellent chapter on malocclusion of the teeth (which subject we also recommend to the medical practitioner, especially the pediatricist), diagnosis of localized swellings of the oral mucosa and lips, and a separate chapter on disease and swellings of the tongue. These last two chapters contain some very fine photographs and color plates. The chapter on *Diagnosis of Oral Foci, Potential Sources of Systemic Disease*, contains the best thought in modern dental circles.

LAWRENCE J DUNN

Disability Evaluation Principles of Treatment of Compensable Injuries By Earl D McBride, M D. Octavo of 623 pages, illustrated. Philadelphia, J B Lippincott Company 1936. Cloth, \$8.00.

The author describes a method for determining the percentage of disability in those victims of industrial accidents. The provisions of the compensation laws, as to disability awards, of Canada and the United States are briefly summarized.

The method used by the author is described in Chapter II. Various schedules are derived from an analysis of the normal functions of a part as related to the industrial activity of the individual. These schedules aid in estimating the functional disability of the injured. The authors' meaning is clearly illustrated by numerous sketches which accompany these schedules.

The examination of the disabled person is fully and specifically outlined. The disabilities of the various joints and the associated factors which determine the amount of loss of function for which the person

ORDERING BOOKS

declares the medical man who separated them, D W McLaren, M B, B S, medical officer of the Colonial Medical Service of Nigeria, in the *British Medical Journal* for Nov 14. He writes

The twins (female), born to a Hausa woman in Sokoto Emirate, were united at the epigastrium by a circular funnel of tissue, which at the operation measured about one and a half inches in width and two inches in diameter. The union was such that the children could be turned away from each other to the extent of about a right-angle only. The sterna formed a continuous U-shaped bar of cartilage about half an inch in width across the top of the isthmus. A small single umbilical scar was visible on the under surface, about its middle. The photograph shows well the site and degree of the junction.

The mother, a healthy, well-developed woman aged about twenty-five, had had previously two normal births, the first six years ago, the child (a boy) dying at the age of ten months, and the second (a girl) now alive and well at the age of five years. The twins were born on December 20, 1935, the estimated time of gestation being about 250 days. Birth was apparently not difficult, though the mother admits that she was in labour for nearly twenty-four hours, which is a relatively long labour for a multiparous native woman. She states that the head of one and the feet of the other presented together and that the cord was single the whole way from the juncture to the placenta, which came away very shortly after the birth of the infants.

The twins were first seen at the age of $2\frac{1}{2}$ months, when they appeared to be rather emaciated and anemic, though quite vigorous. It was then apparent that operation was quite feasible, for by compressing the isthmus between the finger and thumb the bowel of the one or the other could be easily reduced into the abdomen, leaving nothing but integument and the bar of sternal cartilage between the fingers. Since the mother was rather reluctant to agree to operation, it was decided to leave them till the age of six months, when it was hoped that they would be more developed and better able to stand the operation. This hope was fulfilled, for on admission to hospital on May 27, at the age of five months, they had grown into quite normal plump infants, though still anemic. It was more evident now that one was a little more developed than the other.

The blood examination on admission showed a red cell count of 3,600,000 per c.mm. and a hemoglobin index (Tallqvist's scale) of forty per cent. Two weeks on an iron mixture raised the count to 4,310,000 per c.mm., and the hemoglobin increased to 55 per cent. The

mother's blood revealed only a slight degree of hypochromic anemia (compared with the average standard of the normal native), with a count of 5,040,000 erythrocytes and a hemoglobin percentage of 70.

The Operation

On June 16 the operation was performed under chloroform anesthesia, without any preliminary preparation apart from the oral administration of glucose. The stronger twin was anesthetized first in the hope that the other would also go under, but after ten minutes of full anesthetization no obvious effect was observed on the second twin, and she had to be separately anesthetized. The operation presented no great difficulty. The incision was made vertically through the middle of the junction, and on opening the peritoneum it was observed that there was a vertically placed peritoneal septum in the upper half with a "foramen" at the lower part, through which bowel from one or the other could easily pass. The only structure divided, apart from the integument, peritoneum, and the sternal cartilage, was the ligamentum teres of the larger twin's liver, and this was found traversing the upper part of the isthmus extraperitoneally. Its connection with the umbilicus was not traced.

As soon as separation had been effected the infants were placed in the supine position, and each wound was sutured up vertically in turn. No attempt was made to trim the projecting cut edges of the sterna or the skin, and only excess of parietal peritoneum was excised. The rectus aponeuroses were thin and attenuated, but the recti themselves seemed undeveloped in this area, after operation it was evident that this was so, since there was in each around the site of union an oval-shaped area, which was quite devoid of muscular tissue. The gap was about two and a half inches in its widest part, and there was no muscle attachment to the lower ends of the sterna. The cut ends of this have straightened out since the operation, this makes the bulge of the abdominal wall in this area less obvious than it might have been had the sternal ends been resected. There is still the probability, of course, that they will develop large umbilical hernias later.

Apart from a slight attack of enteritis in the weaker infant, and a stitch abscess in each wound, the postoperative period was uneventful. The mother was able to breast-feed the children from the first day. The weights just after the operation were ten and twelve lb respectively, and now, six weeks later, thirteen lb each. The blood count has improved to 4,900,000, and the hemoglobin to 60 per cent, they are now in every way normal and vigorous infants.

though omitting many theoretical considerations, supplies much practical material

In the fourth chapter we find methods of training discussed, the management of various types of cases are clearly set forth and the many definite statements seem to be supported by experience with abundant material. It is not always made clear, however, how the methods of training can be applied to young children

Selection of cases for operation, and results of various methods of treatment follow, and the appendix is devoted to description of instruments

This volume doubtless adds a petal to the unfolding strabismus blossom

JOHN N EVANS

A Text-Book of Pharmacology and Therapeutics or the Action of Drugs in Health and Disease. By Arthur R. Cushny, M D Eleventh edition thoroughly revised by C W Edmunds, M D and J A Cunne, M D Octavo of 808 pages, illustrated Philadelphia, Lea & Febiger, 1936 Cloth, \$6 50

The present edition of this outstanding work on Pharmacology brings it into line with the eleventh decennial revision of the Pharmacopoeia of the United States which became official June 1, 1936

Considerable rearrangement of the order of the book and in the grouping of drugs was made with a view to convenience in teaching the subject and ease of learning it

This classic remains a vade mecum in pharmacology

CHARLES SOLOMON

Lobar Pneumonia and Serum Therapy With Special Reference to the Massachusetts Pneumonia Study By Frederick T Lord, M D and Roderick Heffron, M D Octavo of 91 pages, illustrated New York The Commonwealth Fund, 1936 Cloth, \$1 00

This monograph is propaganda in a good cause. It contains only 91 pages and should be read by every internal medicine practitioner

While we must concede that the authors prove their case, up to a certain point, we must hope that control of pneumonia, by serum or otherwise, may soon be more complete than is now claimed

W D LUDLUM

A Textbook of Histology By Joseph Kraska, Jr, M D Octavo of 246 pages, illustrated Baltimore, The Williams & Wilkins Company, 1936 Cloth, \$2 50

The purpose of this text is to present the subject as a specific entity, separated from its usually associated sciences as far as possible, and has been prepared for other students than those of medicine. The medical student, however, will utilize its content

as a meaty outline. Not having the detailed bulk of a medical text and strictly adhering to microscopic anatomy, it less pedantically and very adequately covers its subject. The chapters on bone marrow and the female reproductive system are specifically excellent contributions. Line drawings and other illustrations are practically entirely original and well produced. The text has a very useful field among more interested students of the social sciences, among student biochemists, and physiologists, and should be particularly useful to tissue technicians who understandingly use microscopes

IRVING M DERBY

Medicine and Mankind Edited by Iago Galdston, M D Lectures to the Laity delivered at the New York Academy of Medicine Duodecimo of 216 pages New York, D Appleton-Century Company, Inc, 1936 Cloth, \$2 00

This book, of 216 pages is composed of an Introduction by Eugene H Pool, M D, President of the New York Academy of Medicine, and seven lectures by outstanding physicians, as follows

- I How We Learned about the Human Body, by Benjamin Watson, M D
- II Medicine in the Days of the Grand Monarch, by Howard Haggard, M D
- III Contributions of the Primitive American to American Medicine, by Harlow Brooks, M D (Posthumous)
- IV The Common Denominator of Disease, by George Draper, M D
- V The Organic Background of Disease, by Foster Kennedy, M D
- VI The Story of the Vitamins, by Elmer V McCollum, Ph D
- VII The Mysterv of Death, by Alexis Carrel, M D

The authors have lived up to the theory of the course in an interesting, polished and erudite style, which has largely overcome the difficulties attendant upon imparting highly specialized knowledge to the uninitiated. The New York Academy of Medicine is to be congratulated upon a scholarly production, which cannot fail to be interesting and instructive to a cultured laity

J M VAN COTT

A Diabetic Manual for Practitioners and Patients By Edward L Bortz, M D Octavo of 222 pages illustrated Philadelphia, F A Davis Co, 1936 Cloth

This manual has the fault of almost all the present diabetic manuals—the lay reader is not equipped to distinguish the material only of value to the doctor or medical student and that written for the patient's guid-

should be compensated, are fully presented. The chapter on the industrial "back" is well treated and illustrated. This cannot be said of the chapter on hernia.

The book should be of value to the industrial surgeon and the general practitioner who may have to present cases before the industrial commission.

RALPH WOLFE

The Harvey Lectures Delivered under the auspices of The Harvey Society of New York, 1934-1935. Series XXX. Octavo of 270 pages, illustrated. Baltimore: The Williams & Wilkins Company, 1936. Cloth, \$4.00.

This is a valuable compendium of the lectures delivered under the auspices of the Harvey Society of New York in 1934 and 1935. They include:

The Etiology of Pernicious and Related Macrocytic Anemias

Dr. Wm. Bosworth Castle

The Significance of the Amino Acids in Nutrition

Prof. William Cumming Rose

The Present Geographic Distribution of Yellow Fever and its Significance

Dr. Wilbur A. Sawyer

Processes of Urine Formation in the Amphibian Kidney

Prof. Alfred N. Richards

Specificity in Relation to Hormone and Other Biological Reactions

Dr. E. C. Dodds

The Relation of the Circulation in Voluntary and Plain Muscle to Activity

Prof. G. V. Anrep

Pneumothorax in the Treatment of Pneumonia

Prof. Francis G. Blake

The Isolation and Properties of Crystalline Pepsin and Trypsin

Dr. John H. Northrop

No progressive student of medicine should fail to read this book.

MAX LEDERER

Synopsis of Diseases of the Heart and Arteries By George R. Herrmann, M.D. Duodecimo of 344 pages, illustrated. St. Louis, C. V. Mosby Company, 1936. Cloth, \$4.00.

This is a concise, practical, little volume primarily intended for the undergraduate in medicine and the busy practitioner. The essential facts in cardiology are clearly presented. The illustrations, particularly those in the section on the cardiac arrhythmias, clearly depict the mechanism of these disorders. The discussion of the differential diagnosis of the valvular diseases is excel-

lent. The therapy is presented in a practical and detailed manner. As the author states in his preface, this volume is not written for the cardiologist. To the medical student it can be recommended for the essential and accepted facts in cardiology.

HENRY JOACHIM

Food, Fitness and Figure. By Jacob Buckstein, M.D. Introduction by Harlow Brooks, M.D. Octavo of 252 pages. New York, Emerson Books, Inc., 1936. Cloth, \$2.00.

This book discusses three main problems—the requirements of the body, overweight, and underweight. Separate chapters are devoted to each of the requirements such as protein, carbohydrates, minerals, and vitamins and the part that they play in body maintenance. Although the style and description is popular and interesting, the facts given are scientific. On the subject of overweight, the author is definitely conservative in his advice and does not resort to any drastic steps for loss of weight either in the written matter on the subject or in the prescribed dietary regime which he outlines in detail for a period of fourteen days. The menus given appear to be adequate in all nutritional requirements. He follows this by the same type of outline of regime for the underweight individual.

This work is commendable in that it acquaints the persons seeking this information with a scientific point of view which is tempered by conservatism rather than radicalism which has been the fallacy of so many of our former weight reducing regimes.

MORRIS ANT

Squint Training By M. A. Pugh, M.R.C.S. Octavo of 117 pages, illustrated. New York, Oxford University Press, 1936. Cloth, \$2.75.

The renaissance of interest in the "squint problem" is once again emphasized by the appearance of this little volume.

Miss Pugh is the Medical Officer in charge of the Ophthalmic Department at the Royal London Ophthalmic Hospital. The book discusses in a brief form, causes, pathology (mostly theory) and treatment of squint.

The first chapter discusses the classification of squint as accepted by the author. From the reviewer's point of view this chapter should be elaborated.

The second chapter on preliminary investigation is short but is worthwhile. It refers to some of the methods of measuring squint but does not go into the technique in sufficient detail to permit the beginner to proceed without supervision.

The third chapter on binocular vision,

LOBAR PNEUMONIA IN CHILDHOOD

A Five and a Half Year Clinical Survey at a Municipal Hospital

SAMUEL L. ELLENBERG, M D and ALEXANDER T. MARTIN, M D, *New York City*

From the Pediatric Service of Lincoln Hospital

During the past decade comparatively few clinical or statistical surveys of lobar pneumonia in children have appeared in the literature. This is indeed surprising, for one would not venture to say that this subject is barren of interest, especially in view of the interesting, stimulating, and thought-provoking studies of Griffith¹ in the United States and McNeil² in Great Britain which once again demonstrated that our knowledge of lobar pneumonia in children can always be added to. We, therefore, feel that the present comparative study of lobar pneumonia in children at a Municipal hospital covering a five and a half year period will be of interest to the general practitioner and the pediatricist.

Age

During a five and a half year period covering January 1930 to June 1935, 459 cases of lobar pneumonia were admitted to the Children's Wards of Lincoln Hospital, eighty-nine of these cases were one year and under, and forty-eight cases were between one and two years, so that thirty per cent of the total number admitted were under two years of age. Further statistical study showed that forty per cent of the total were under three years of age, while fifty per cent of the cases were under four years. The smallest number of cases were recorded in the ninth, tenth, eleventh, and twelfth years

of life, while the peak incidence was reached in the first year of life as indicated by Chart I.

Sex

Lobar pneumonia appeared to be more prevalent in our series among the male children, inasmuch as 260 males were affected as compared with 199 females. These findings agree with the few figures recorded in literature. Moody found in his series that 195 males and 180 females were affected.

Season

The greatest number of cases were recorded during the late winter months and the greatest morbidity for the entire five and one-half year period occurred during the month of March with April coming a close second, while the smallest number of cases were noted in July. It is interesting to note that during the period of this clinical study, the peak of cases each year was recorded in different months, thus in 1930, April was the peak, in 1931—January, in 1932 it was December, in 1933—October, in 1934—March, and in 1935—May (Chart II).

Mortality

The mortality at Lincoln Hospital, despite the fact that it is a municipal hospital, and that crowded children's wards

ance The reader is not given the fundamental factor of successful treatment of diabetes, the requirement that the patient be under the supervision of a physician or a clinic whose word he can accept without doubt, argument, or even explanation

There has been too much attempt to educate the patient far beyond his ability "A little knowledge is a dangerous thing"

It is hoped that in the future an effort will be made to present simple general statements to the patient and to avoid the error of writing manuals for use of physician and patient.

Of interest is the grouping of carbohydrate foods in units compared with a lump of sugar or 3 grams Rabinowitch of Montreal uses a slice of bread, carbohydrate 18 grams, as a unit Beardwood and Kelly in Philadelphia have a unit of 5 grams carbohydrate In the Brooklyn Hospital group the unit of carbohydrate is 10 grams

There is a definite trend to use household measures and to get away from the percent value of food stuffs It is reasonable to expect that a uniform standard carbohydrate unit will be adopted by physicians treating diabetics throughout the country

PAUL C ESCHWEILER

A Manual of Practical Obstetrics By O'Donel Browne, M B Octavo of 363 pages, illustrated Baltimore, William Wood and Company, 1936 Cloth, \$6 50

An excellent book, not intended to take the place of more comprehensive works, it is exactly what it sets out to be, a practical manual as good as anything ever published The style is simple and direct, and the teaching very conservative In Occipito-posterior positions delivery is completed with forceps for the same indications as when the occiput is anterior, and slow labor is disregarded The Dublin theory and treatment of eclampsia are set down in detail, and on the whole the book is representative of the conservative Dublin School For the general practitioner the book is admirable.

CHARLES A GORDON

Heart Disease and Tuberculosis Efforts Including Methods of Diaphragmatic and Costal Respiration to Lessen Their Prevalence By S Adolphus Knopf, M D Octavo of 108 pages, illustrated Columbia County, New York, The Livingston Press 1936 Cloth, \$1.25

This little volume is a recapitulation of views presented by various authors respecting the prevalence of tuberculosis and heart disease, emphasizing the prophylactic measures in vogue at the present time. It is a book of great value to the social worker, bringing the economic aspect home to the

patient, the welfare agency and the public. It is an up-to-date treatise upon the sociological aspect of the two great scourges of the human race, tuberculosis and heart disease

SIMON FRUCHT

International Clinics A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, Neurology, etc Edited by Louis Hammann, M D Volume 2, 46th Series, 1936 Octavo of 327 pages, illustrated. Philadelphia J B Lippincott Company, 1936 Cloth, \$3 00

This volume maintains the standard of previous issues of the Clinics The digestive tract has been treated surgically by an article on surgical diseases of the gastrointestinal tract in children and one on surgical management of colonic carcinoma

The field of medicine has been generously covered from the effects on health and disease of climatic conditions, diet in treatment of heart disease, hemophilia, nutritional edema, extracellular body fluid to an explanation of the erythrocytic sedimentation test These articles are of unusual interest and will repay a careful study

HENRY M MOSES

Vascular Disorders of the Limbs. Described for Practitioners and Students By Sir Thomas Lewis, M D Octavo of 111 pages New York, The Macmillan Company, 1936 Cloth, \$2 00

This book of 111 pages presents a readable account of vascular diseases of the extremities, written by an expert in clinical research, but for students and practitioners Because it is offered to such readers, the author has stressed only such tests and methods of examinations as can be readily used by clinicians

A consideration of the pathology and treatment of phlebitis, varicose veins and aneurysms has been omitted by the author for valid reasons, but it would seem that the omission of the description of these more common conditions by such a gifted investigator is a great loss to the class of readers to whom this work is addressed

J RAPHAEL

A Study of Masturbation and the Psychosexual Life By John F W Meagher, M D Third edition re-edited and revised by Smith Ely Jelliffe, M D Duodecimo of 149 pages Baltimore, William Wood & Company, 1936 Cloth, \$2 00

This little book now in its third edition is a very sane and sensible discussion of masturbation, with all its various physical, moral and psychic implications It is of particular interest to the psychiatrist

N P RATHBUN

LOBAR PNEUMONIA IN CHILDHOOD

A Five and a Half Year Clinical Survey at a Municipal Hospital

SAMUEL L. ELLENBERG, M D and ALEXANDER T. MARTIN, M D, *New York City*

From the Pediatric Service of Lincoln Hospital

During the past decade comparatively few clinical or statistical surveys of lobar pneumonia in children have appeared in the literature. This is indeed surprising, for one would not venture to say that this subject is barren of interest, especially in view of the interesting, stimulating, and thought-provoking studies of Griffith¹ in the United States and McNeil² in Great Britain which once again demonstrated that our knowledge of lobar pneumonia in children can always be added to. We, therefore, feel that the present comparative study of lobar pneumonia in children at a Municipal hospital covering a five and a half year period will be of interest to the general practitioner and the pediatricist.

Age

During a five and a half year period covering January 1930 to June 1935, 459 cases of lobar pneumonia were admitted to the Children's Wards of Lincoln Hospital, eighty-nine of these cases were one year and under, and forty-eight cases were between one and two years, so that thirty per cent of the total number admitted were under two years of age. Further statistical study showed that forty per cent of the total were under three years of age, while fifty per cent of the cases were under four years. The smallest number of cases were recorded in the ninth, tenth, eleventh, and twelfth years

of life, while the peak incidence was reached in the first year of life as indicated by Chart I.

Sex

Lobar pneumonia appeared to be more prevalent in our series among the male children, inasmuch as 260 males were affected as compared with 199 females. These findings agree with the few figures recorded in literature. Moody found in his series that 195 males and 180 females were affected.

Season

The greatest number of cases were recorded during the late winter months and the greatest morbidity for the entire five and one-half year period occurred during the month of March with April coming a close second, while the smallest number of cases were noted in July. It is interesting to note that during the period of this clinical study, the peak of cases each year was recorded in different months, thus in 1930, April was the peak, in 1931—January, in 1932 it was December, in 1933—October, in 1934—March, and in 1935—May (Chart II).

Mortality

The mortality at Lincoln Hospital, despite the fact that it is a municipal hospital, and that crowded children's wards

made adequate nursing care difficult, compares quite favorably, nevertheless, with the mortality statistics reported in the literature by other observers. Of the 459 lobar pneumonia patients forty were claimed by death—a mortality percentage of 8.6 per cent. This mortality percentage

CHART I

CHART II

could be decreased much further if the noninstitutional deaths, (i.e. deaths occurring less than 48 hours after admission) could be discounted. It must be remembered that any municipal hospital receives a great number of cases which are sent in to it as a last resort measure with a consequent increase in the noninstitutional death statistics. Subtracting the noninstitutional deaths which were eighteen, from the total number of deaths, forty, we arrive at the true mortality rate of 4.7 per cent.

Grulee and Mulherin² report in their series of 116 cases of lobar pneumonia a mortality of seven per cent. Morgan⁴ in his report of 398 cases of lobar pneumonia records a mortality of 9.3 per cent. Moffat found 12.9 per cent mortality in cases believed to be lobar pneumonia while Manace⁵ reported a 9.7 per cent mortality, and Moody⁶ also reported a mortality of 9.6 per cent in his series.

The fact that the mortality is higher in children two years and under is also borne out by this study, for the mortality in this age group is twenty-four per cent as compared to a mortality of 2.1 per cent in the age group above two years. Of the forty deaths in the entire series, thirty-three were two years of age and under, and, of these twenty-six were one year and under. Nemir⁷ reported a mortality of twenty per cent in infants under two years as contrasted with a mortality rate of five per cent in children over two at the Bellevue Hospital Children's Division (this hospital treats approximately the same type of patients as at Lincoln Hospital). Albert⁸ reported 19.2 per cent mortality in children under three years in the Philippine Islands.

X-ray

X-ray films were taken in 306 cases and were not available in the balance of the series either because the child was too ill to be taken to the x-ray room, too ill to be disturbed for portable plates, or because the ward was under quarantine for some contagious disease. In 220 of the patients the x-ray findings agreed with the diagnosis, but in eighty-six cases, or twenty-one per cent the x-ray films were at variance with the clinical impres-

sion, the reports simply reading "No evidence of lesion of lungs"

In the majority of cases where the x-ray was reported as negative, it was, unfortunately, not repeated. Possibly further repetition might have revealed evidence of consolidation in some of these cases, and it is also likely as Charles Hendee Smith⁹ pointed out, that an eccentric x-ray plate might have revealed evidence of consolidation where such consolidation was obscured by the heart shadow. In some instances where x-ray films were taken at intervals during the state of clinical consolidation, confirmatory x-ray evidence was finally obtained, even though the first x-ray film had been negative. However, in still

heart with congestion of the lungs simulated lobar pneumonia, or where a differential diagnosis between a pathological process in the lungs or in the abdomen presented itself the x-ray was found helpful in most, but not all, instances.

A considerable proportion of the positive x-rays in this study showed a partial rather than complete consolidation of the lobe. This is believed to be characteristic of lobar pneumonia in children. The time honored controversy as to whether the pneumonic process begins at the periphery or the hilum of the lung is settled so far as our own series is concerned, in favor of the spread of the pneumonic process from the hilum to the periphery. This conclusion is accounted

**Mortality 2 years and under group = 24%

other cases, repeated x-ray films throughout the course of the illness were consistently reported negative despite the definite physical findings of consolidation.

Manace found the clinical diagnosis of lobar pneumonia confirmed in ninety out of ninety-two cases by x-ray. Bromer¹⁰ found in his series eighty-five out of a hundred cases of lobar pneumonia were confirmed by x-ray. Albert reported that the x-ray examination was positive in 125 cases, negative in eight cases, and not definite in sixteen cases. The fact that a considerable number of the x-rays were reported as negative in our series appears to be at variance with the figures recorded by these and other observers, but seems to be in conformity with the critical conclusion of J. C. Grozier Griffith who found that the x-ray was not as reliable as it had been previously considered.

It is of interest that in our series in only few instances did the x-ray reveal pathology which had not been considered clinically. Nevertheless, where a failing

for by the preponderance of involvement of the lower lobes. In the involvement of the lower lobe the x-ray report most frequently obtained was that of "a shadow in the lower and inner portion of the right (or left) lung field" whereas in the involvement of the upper lobe "a triangular wedge-shaped shadow in the outer part of the upper lobe" would be reported.

In some cases, the x-ray film revealed more lung pathology and other times less than was obtained from the physical findings. It might be mentioned in passing, that it was difficult to tell from an A-P view whether involvement of the upper part of the right lower lobe had occurred, or whether the right middle lobe was involved.

Errors in Diagnosis

Of the 459 cases, 114 did not present sufficient physical findings of lobar pneumonia to warrant such a clinical diagnosis on admission. As indicated in Table II the diagnosis considered in these cases in their order of frequency were upper respiratory infection, acute tonsillitis, acute bronchitis, and otitis media. In distinct contrast to this, in only twelve instances was a diagnosis of lobar pneumonia erroneously made on admission (Table III).

In the early stage of lobar pneumonia, the location of the pneumonic process was not always a simple matter, in fact, different observers examining the patient at the same time varied in their opinion as to the lobe affected, and it was not at all unusual for a child to have his pneumonia for three to four days before a general agreement would be reached among the staff with respect to the consolidated portion of the lung, of course, by that time, the physical signs were so clear-cut as to permit accurate localization.

When physical signs were obtained in the upper half of the lung field posteriorly it was difficult to be sure whether the upper lobe was affected, or whether the upper half of the lower lobe was involved by the pneumonic process.

The physical signs of consolidation came out anywhere from one to eight days after admission. Only occasionally would a

case be admitted in the state of resolution. When this happened the usual diagnosis on admission was that of bronchopneumonia because of the scattering of the physical signs in the lung.

The presence or absence of fluid could not always be clearly determined on the basis of physical signs. In a number of instances when the physical signs indicated the probable presence of fluid chest taps would prove to be unfruitful. On the other hand, in other cases when the signs in the chest came through clearly, but flatness was present, chest taps did reveal fluid.

Although the clinical appearance of the patient was helpful in giving a clue as to the probability of the child having pneumonia, it was not always a reliable guide since a number of our cases were amazingly comfortable despite a high temperature, rapid pulse, and even with the involvement of two or more lobes.

Meningismus

Meningeal irritation was noted in twenty-four patients and in these cases a lumbar puncture was performed. Invariably the spinal fluid was obtained under increased pressure and was colorless, clear, and contained the normal number of cells and did not reveal any microorganisms. Meningeal irritation was found to be most frequently associated with involvement of the right upper lobe. It was noted in thirteen cases of right upper lobe pneumonia, in five cases of lower lobe pneumonia, and in one case of right middle lobe pneumonia. It is of interest that a few of these cases continued to show meningeal irritation for a week or more with consistently negative lumbar punctures.

Blood

A leukocytosis was invariably reported in our cases with a preponderance of polymorphonuclear cells and definite shift to the left of the Schilling hemogram when the latter was performed. Although most writers feel that a lower leukocyte count indicates a poor prognosis, we were not particularly impressed by this finding since most of our fatal cases showed leukocytosis with the expected usual shift to the left.

The erythrocyte sedimentation rate was always rapid in the acute stage of the pneumonic process and was not of any diagnostic significance in our series.

Complications

The five most frequent complications in their order of frequency in our study were otitis media, empyema, mening-

empyema came next with an incidence of 64 per cent. Holt¹¹ reported eight per cent developing empyema. Hill¹² noted, among 1187 cases of pneumonia children up to two years, otitis media ran first twenty-eight per cent, empyema four per cent, pyelitis two per cent, and acute nephritis one per cent, in children from two to twelve, otitis media occurred in

gismus, furunculosis and abscesses, and pleurisy. Although, according to Table IV, measles appeared in fourteen of the pneumonia patients, these occurred only during epidemic periods.

Otitis media occurred in twenty-one per cent of the cases, and empyema in 69 per cent of the cases. Moody also found otitis media to be the most common complication in an even higher percentage, namely thirty-four per cent, and

fifteen per cent of the cases, empyema five per cent and unresolved pneumonia two per cent.

Treatment

The majority of the patients in our series recovered uneventfully without the need of any unusual treatment, the routine order for these cases consisted of liquid diet, forcing of fluids, application of ice cap to the head, sponging for tempera-

tures of 103° F and above, and soap suds enema when necessary

It was noted that distension of the abdomen required most frequent attention, occurring in thirty-five cases, and this as a rule, responded to the use of turpentine stupes, rectal tube, occasional use of pituitrin, and various medicated enemas. Thirty-two of the patients required supportive treatment such as hyperdromoclyses of normal saline of three to five per cent glucose, and infusions of five to ten per cent glucose. Surgery was resorted to in twenty-nine cases either for the relief of purulent fluid in the pleural cavity or the incision and drainage of furuncles and abscesses. Apparently only twenty-nine cases were considered as needing oxygen. Sedatives such as codeine, phenobarbital, sodium amytal, etc were used in twenty-six cases. Transfusions were given in eighteen cases, the amount given being usually based on the rule of ten c.c. per lb of body weight.

Stimulation in the form of drugs like adrenalin, caffeine, sodium benzoate, etc were used in seventeen patients. Other therapeutic procedures as counter irritation, lumbar punctures, chest taps stomach lavage, postural drainage, anti-anemic measures, and insulin were used very little.

Prognosis

The prognosis of lobar pneumonia under the age of two was found to be almost as bad as that of bronchopneumonia. Over the age of two, a good prognosis could be given in the great majority of the patients. The length of hospital stay could not be accurately determined in our series because a number of the patients were kept confined to the hospital because of quarantine regulations during episodes of contagious illnesses, or were compelled to wait until arrangements for their transfer to a convalescent home could be made, or had to be kept on the wards until such time as they could be taken care of at home.

Discussion

Anyone who makes a clinical and statistical survey of lobar pneumonia in children becomes definitely impressed

with the extremely high incidence of the disease in the younger age group. This fact has been noted by every observer who has reported on studies of lobar pneumonia in children, thus Minten, Bailey, and DeBone¹⁸ comment on the high incidence of children under six, with especial frequency in those under two. McNeil discussing acute pneumonia in early childhood found 110 cases in the first year, 146 in the first and second years, seventy between two and three, seventy-six between three and five, and ninety-five between five and twelve years.

Manace in ninety-two cases of lobar pneumonia found twenty-four in the first year, twenty-nine in the second year, and thirty-nine cases over two years.

Morgan reporting 398 cases of lobar pneumonia stated that sixteen per cent of his patients were under one year of age, nineteen per cent were between one and two, and forty-seven per cent were under three years of age.

Lamont also declared that pneumonia in children was most frequent in the first year, the second year was next in frequency, while between six and ten the incidence diminished.

The predominance of pneumonia in boys may be accounted for by their greater activity and their love of play in all kinds of weather, their scornful neglect of the "common cold," and by the little care usually given by the male child to his personal hygiene.

It has long been established that the greatest morbidity in lobar pneumonia in this region is recorded in the late winter months. It is of interest, however, to note that the peak of pneumonia for each year may vary greatly from that of other years and is dependent upon the climatic conditions, the diminution of the resistance of the individual by other infections, and the virulence of the organism responsible for the pneumonia.

In the present study the x-ray proved to be merely of confirmatory value for it rarely revealed consolidation which had not been clinically suspected. The fact that in twenty-one per cent of our cases the x-ray was negative at the time when lobar pneumonia was clinically diagnosed on the basis of physical signs is worthwhile considering especially in view of

the reports in the literature which lead one to believe that the x-ray is positive in most cases of lobar pneumonia. The careful roentgenologist admits that clinical data is essential to the absolute diagnosis of pneumonia, the x-ray findings being purely confirmatory.

Our x-ray findings are not in agreement with those of Davis and his associates¹⁴ who state that a radiograph twenty-four-forty-eight hours after the onset of pneumonia, should show unmistakable signs if pneumonia is present. Wesler and Jaches also declare that in the earliest states of lobar pneumonia encountered clinically, even before clinical signs are present, well-marked shadows are already to be seen.

Bromer in discussing the fifteen negative x-rays obtained in his series of 100 cases felt that the explanation for the negative x-rays might be among the following:

- 1 Clinical diagnosis may have been in error
- 2 Some of the cases may have had the consolidation concealed by the heart shadow
- 3 Pneumonic lesions may be so small or located in the center of the lung field as not to cast a shadow through the air filled lung about them

Attention should also be called to the fact that in the stage of engorgement the x-ray will only show increased hilus markings and a hypervascularization. It is when the exudate is poured into the alveoli that a shadow is cast on the film and, as Charles Hendee Smith pointed out, some exudates may not contain enough fibrin to stop the penetration of the x-rays.

Moody after noting, that in eighteen of the lobar pneumonia cases autopsied, only in five cases did the x-ray, clinical, and postmortem findings agree, came to the same conclusion previously reached by Griffith in 1928 (the latter had reported twenty-six cases of pneumonia which had been classified clinically, diagnosed by x-ray, and examined at postmortem and found that the three diagnoses agreed in only six cases) namely, that in the early stage the clinical picture and course gives the most accurate estimate of the condition.

We have been impressed by the fact

that a considerable number of our cases (114) did not reveal any physical signs in the lungs on admission to the hospital, but that these physical signs appeared twenty-four-forty-eight hours later, in some cases not until the seventh-eighth day of hospital stay. Mason has already called attention to the fact that the physical signs will not be elicited in the lungs until the pneumonic process is present at the hilum. From the fact that so many of these cases were considered to have an upper respiratory infection on admission and then later showed unmistakable signs of pneumonia, it would behoove the general practitioner, or the pediatricist to guard his prognosis in upper respiratory infections and be on the lookout for a pneumonic process if the patient does not improve as expected. The error of considering a patient to have lobar pneumonia on admission was committed much less frequently—in fact in only twelve cases did the subsequent course reveal that an incorrect diagnosis of lobar pneumonia had originally been made. Meningismus was most frequently noted in involvement of the right upper lobe which is in agreement with the impression of Koplik and Morgan, who stated that "cerebral pneumonia most frequently affected the right upper lobe."

Only a very small number of our patients showed any delay in resolution. Some writers question whether such a condition as delayed resolution exists, maintaining that any pneumonic condition lasting longer than fourteen days is not a lobar pneumonia but a bronchopneumonia.

Of the complications, the most serious and the most likely to influence the course of the illness is that of empyema. Although it ranks second in frequency it gives more trouble than the more common complication of otitis media. In the study of the effect of this complication in childhood, McNeil found that in the first year, empyema brought about a fatal issue in 77.7 per cent of the infants developing this complication, 42.8 per cent in those between one and two years as contrasted to 11.1 per cent in children between two and three years, and four per cent in the age group between five and twelve.

A great deal has been written about the treatment of lobar pneumonia in children with each enthusiast advocating his particular method of therapy as the one productive of the best results. However, calm, unbiased observers, after carefully analyzing their own cases and those of others reported in the literature, have invariably come to the conclusion that in the majority of cases the child with lobar pneumonia is best left alone with careful nursing.

The consensus of opinion in the literature is that fresh air (such as is obtainable in any well-ventilated room), a liquid diet, consisting mostly of fruit juices, water, malted milk, modified milk, the forcing of fluids, the opening of the bowels by means of a good cathartic such as castor oil, mineral oil, and milk of magnesia, or a soap suds or bicarbonate of soda enema, or colonic irrigation, the sponging with tepid water when hyperpyrexia is present, the use of an ice cap to the head, counter irritation such as application of a light poultice or mustard plaster when pleuritic pain is present is all that is necessary in most cases of lobar pneumonia.

Grulee and Mulherin particularly emphasize that the patient be left alone and insist that all drug treatment be dispensed with as far as possible. Kochmann¹⁵ also states that for the majority of children with pneumonia, proper nursing care and hygiene give the best results.

Sedatives are necessary at times to secure the proper rest which is essential in pneumonia. Those commonly used are codeine, phenobarbital, bromides, and morphine. In older children where an inadequate food intake is noted, either because of inability of patient to take food, or refusal to take it, this has to be supplemented by aid of clyses of normal saline or three to five per cent glucose or by infusion of five to ten per cent glucose (Schroeder advocates six to ten per cent glucose giving ten c c per lb of body weight up to a total of 300 c c).

Where the cough is excessive, wearing, and disturbing to the child's rest, it should be controlled with codeine or with atropine. Where cardiac stimulation is found to be necessary, drugs as alpha-lobelin, camphor in oil, caffeine, sodium

benzoate, adrenalin, and digitalis are helpful. The use of digitalis in children has been generally considered to be of no value, even its advocates admitting its use limited to cases where auricular fibrillation has set in or where evidence of cardiac decompensation is present and when it is used, should be used to full digitalization.

Oxygen is considered to be a very definite adjuvant to the treatment of pneumonia and should be used whenever cyanosis, excessive restlessness, hyperpnea or severe toxemia is present. The old method of giving oxygen by nasal catheters or by means of an open funnel has never convinced us that it has done any real good, in fact, we have felt that these methods of employing oxygen were really the cause of the restlessness of the child. However, we agree with most observers that with the use of the child oxygen tent, oxygen is a very helpful therapeutic aid.

Transfusions as a therapeutic measure has been a moot point among internists and pediatricists. There are those who have been afraid to transfuse their patients for fear of overburdening the circulation and embarrassing an already overworked right heart, but Schroeder¹⁶ reported thirty per cent of his 225 patients were transfused with invariably beneficial effects and no untoward effect, using ten c c of blood per lb of body weight and no more than 250 c c at a time. In our series, only eighteen patients received transfusions but these were considerably benefited by its use. In the acute stage of pneumonia, we feel a transfusion should be given only for the very toxic or severely anemic patient. After ten to fourteen days of continued pneumonia, a transfusion will help as a stimulus to overcome what appears to be a protracted or unresolved pneumonia and will also hasten convalescence.

Distension is a complication of pneumonia which the physician does not like to see since it is a definite handicap to the patient. De Sanctis¹⁷ feels that raw cow's milk fed in the early stages of pneumonia leads to distension and advocates the use of malted milk rather than milk. Others contend that toxemia is a cause of the distension. When present the usual method of turpentine stupes to the abdo-

men, rectal tubes, use of pituitrin or medicated enemas will combat this condition Kerr advocates the use of stomach lavage since he feels the distension is due in many cases to gastric dilatation alone Other observers feel that the daily feeding of ten to twenty-five grams of salt will help prevent distension, or aid in its treatment.

Attention has lately been focused on the use of antipneumococcic serum in pneumonia in childhood The concensus of opinion, however, is that the good prognosis of lobar pneumonia in children over two makes the use of serum in this age group unnecessary Nemir in her study of the use of antipneumococcic serum in the pneumonias of childhood found that the antipneumococcic sera for Type I and XIV were quite effective and since a large percentage of the pneumonia cases fall in these two groups they can, therefore, be given the benefit of the sera Her statistics show a lowering of the mortality rate in the combined treated cases of lobar pneumonia and bronchopneumonia, nevertheless, her figures in a relatively small series of cases do not show much difference between the mortality in the serum treated and the untreated cases of lobar pneumonia, but her observation that the complications in the treated group were lessened and the duration of the illness shortened are worthy of note

The use of artificial pneumothorax as a therapeutic measure in children is receiving considerable attention at the present time However, it is not as enthusiastically advocated in the treatment of lobar pneumonia in children as it seems to be in adults, even by those who are most enthusiastic in its employment in the treatment of lobar pneumonia

The problem which still remains open, and should enlist the investigation of our keenest clinicians and scientists, is the relatively high mortality of lobar pneumonia in infancy More effective therapeutic measures, than are at the present time available, are to be desired in this age group, that is, in the first and second year of life

Summary

1 A five and one-half year clinical survey of 459 cases of lobar pneumonia in

children admitted to Lincoln Hospital, a general municipal hospital, is presented

2 Lobar pneumonia has a very high incidence in children in the early years of life and appeared to be more prevalent among boys than girls

3 In the early stages of lobar pneumonia the diagnosis could not be made with certainty in about twenty-five per cent of the cases On the other hand, the error of considering a case as lobar pneumonia was very infrequently committed

4 The x-ray was of value as a confirmatory agent in the establishment of the diagnosis of pneumonia, but rarely did it reveal pathology that had not already been considered clinically, and in twenty-one per cent of the cases in our series the initial x-ray was negative

5 Empyema, although second in frequency as a complication of lobar pneumonia, is the most serious and the most likely to influence the course of the illness

6 The prognosis of lobar pneumonia in children under two is serious, in fact, almost as bad as bronchopneumonia, but it is good in children over the age of two

7 The most effective treatment of lobar pneumonia consists in the main of leaving the patient alone with good nursing care Efforts should, however, be made by all investigators to devise more effective therapeutic measures for treating lobar pneumonia in the age group under two where the mortality is highest

A great deal has been written about the treatment of lobar pneumonia in children with each enthusiast advocating his particular method of therapy as the one productive of the best results. However, calm, unbiased observers, after carefully analyzing their own cases and those of others reported in the literature, have invariably come to the conclusion that in the majority of cases the child with lobar pneumonia is best left alone with careful nursing.

The consensus of opinion in the literature is that fresh air (such as is obtainable in any well-ventilated room), a liquid diet, consisting mostly of fruit juices, water, malted milk, modified milk, the forcing of fluids, the opening of the bowels by means of a good cathartic such as castor oil, mineral oil, and milk of magnesia, or a soap suds or bicarbonate of soda enema, or colonic irrigation, the sponging with tepid water when hyperpyrexia is present, the use of an ice cap to the head, counter irritation such as application of a light poultice or mustard plaster when pleuritic pain is present is all that is necessary in most cases of lobar pneumonia.

Grulee and Mulherin particularly emphasize that the patient be left alone and insist that all drug treatment be dispensed with as far as possible. Kochmann¹⁵ also states that for the majority of children with pneumonia, proper nursing care and hygiene give the best results.

Sedatives are necessary at times to secure the proper rest which is essential in pneumonia. Those commonly used are codeine, phenobarbital, bromides, and morphine. In older children where an inadequate food intake is noted, either because of inability of patient to take food, or refusal to take it, this has to be supplemented by aid of clyses of normal saline or three to five per cent glucose or by infusion of five to ten per cent glucose (Schroeder advocates six to ten per cent glucose giving ten c c per lb of body weight up to a total of 300 c c).

Where the cough is excessive, wearing, and disturbing to the child's rest, it should be controlled with codeine or with atropine. Where cardiac stimulation is found to be necessary, drugs as alpha-lobelin, camphor in oil, caffeine, sodium

benzoate, adrenalin, and digitalis are helpful. The use of digitalis in children has been generally considered to be of no value, even its advocates admitting its use limited to cases where auricular fibrillation has set in or where evidence of cardiac decompensation is present and when it is used, should be used to full digitalization.

Oxygen is considered to be a very definite adjuvant to the treatment of pneumonia and should be used whenever cyanosis, excessive restlessness, hyperpnea or severe toxemia is present. The old method of giving oxygen by nasal catheters or by means of an open funnel has never convinced us that it has done any real good, in fact, we have felt that these methods of employing oxygen were really the cause of the restlessness of the child. However, we agree with most observers that with the use of the child oxygen tent, oxygen is a very helpful therapeutic aid.

Transfusions as a therapeutic measure has been a moot point among internists and pediatricists. There are those who have been afraid to transfuse their patients for fear of overburdening the circulation and embarrassing an already overworked right heart, but Schroeder¹⁶ reported thirty per cent of his 225 patients were transfused with invariably beneficial effects and no untoward effect, using ten c c of blood per lb of body weight and no more than 250 c c at a time. In our series, only eighteen patients received transfusions but these were considerably benefited by its use. In the acute stage of pneumonia, we feel a transfusion should be given only for the very toxic or severely anemic patient. After ten to fourteen days of continued pneumonia, a transfusion will help as a stimulus to overcome what appears to be a protracted or unresolved pneumonia and will also hasten convalescence.

Distension is a complication of pneumonia which the physician does not like to see since it is a definite handicap to the patient. De Sanctis¹⁷ feels that raw cow's milk fed in the early stages of pneumonia leads to distension and advocates the use of malted milk rather than milk. Others contend that toxemia is a cause of the distension. When present the usual method of turpentine stupes to the abdo-

times, the term "drug eruption" seems to be most suitable as a general expression for either one

Past Theories on the Pathogenesis of Drug Eruptions

Various theories came into vogue to explain the reason for development of drug eruptions. For instance, the "saturation of the system" due to faulty elimination particularly by the kidneys, the "elective affinity" of drugs for special anatomical elements, the "irritation" of the skin due to the circulating drug, and several others like "modification of the sweat," and the conception that drugs arriving in the blood underwent chemical transformation, the products of which lead in certain individuals to cutaneous lesions (Behrend's "Dynamic Action"). Because these theories had only a limited application, another, the nerve origin of drug eruptions seemed to appeal more to Morrow.² A more modern version is that such skin manifestations are produced through the action of drugs on the endocrines which influence the central and peripheral nervous system

Idiosyncrasy to Drugs

Much that is known today of the clinical characteristics and histological structure of drug eruptions dates from the early studies of this aspect of the question, by the older dermatologists. The theories advanced on the pathogenesis of drug eruptions previously mentioned, were found lacking in their general application and failed to gain general approval. Most observers held to the idea of idiosyncrasy even though its nature remained unrevealed, and considered the display of intolerance of certain individuals to substances generally harmless to others as due to an inherent or inborn peculiarity of the individual.

This was the state until thirty-five years ago when Josef Jadassohn began to publish his studies of idiosyncrasy as noted in drug eruptions.³⁻⁷ Early in his investigations, he indicated that there existed a close analogy between the *modus operandi* of these dermatoses and eczematous dermatitis. In one case for example, Jadassohn noted that areas of the skin that had presented a dermatitis after

the external use of calomel powder and a mercury plaster remained unaffected, in contrast to the dermatitis that developed in other areas of the skin, when mercury tannate was given by mouth. The idiosyncrasy that had developed from the use of mercury was demonstrated to be specific for that drug, irrespective of the preparation used or the method of administration. Besides this, Jadassohn showed that those areas of the skin previously hypersensitive, had developed a "local immunity." Observations on dermatitis from other drugs (iodoform, salol, etc.) definitely convinced him of the close relationship between drug eruptions, especially those of the eczematous type, with the dermatitis produced by other drugs and chemicals.

Jadassohn referred to hypersensitivity that could be specific and nonspecific (polyvalent), and not only indicated but also utilized therapeutically the process of desensitization in dermatoses from drugs. This placed the understanding of idiosyncrasy to drugs on an immunobiologic basis. It was in the eczematous drug eruptions that he employed his test for the functional behavior of the skin—"funktionellen prufung"—now called the "patch test."

Sensitizing Properties of Drugs

As Klauder⁸ indicates, it is doubtful for all drug eruptions to be regarded as manifestations of the same process. The type of pigmentation that may follow the use of the metallic drugs like arsenic, bismuth, gold and silver, etc., is apt to appear in all with prolonged and sufficient dosage because this is primarily due to the deposit of the circulating metal (or its compounds) in the skin. The irritating effects of these cutaneous deposits may lead to the formation of keratoses. The cutaneous lesions from bromides and iodides are based on the displacement of the chlorine ions in the tissues by these halogens, yet individual susceptibility seems to be a factor of importance in those who develop not only the granulomatous and tuberculous bromo or iododermas, but also the acneiform and other eruptions due to these drugs. Milian dismisses all other causes of his "Ninth Day Erythema" from certain drugs, and

ROLE OF ALLERGY IN DRUG ERUPTIONS

E WILLIAM ABRAMOWITZ, M D, New York City

From the Department of Dermatology and Syphilology, New York Post-Graduate Medical School, Columbia University, under the direction of Dr George M MacKie

The purpose of this paper is to discuss the role of allergy in the pathogenesis of drug eruptions. Some of the older theories advanced as an explanation of these skin manifestations will be mentioned briefly in passing.

Historical

The interest in drug eruptions dates back to the eighteenth century and probably originated as a result of the division of opinion that held sway during the preceding three centuries regarding the value of mercury as a cure for syphilis. Some of the toxic symptoms induced by this drug were known to early European medicine from the observations of the physicians of old India, Persia, and Arabia. This knowledge was strangely retarded for many years after syphilis made itself manifest. For instance, the "Antimercurialists" who grew to influential proportion in the profession, and also those who theorized that syphilis was only a mild cutaneous illness, erroneously portrayed eruptions and other manifestations that were due to syphilis as the so-called symptoms of "Mercurial disease." The belief in this phantom abetted by the famous John Hunter was ultimately abandoned, but not until a more rational knowledge of syphilis and its treatment developed, *pari passu* with a better understanding of drug eruptions in general and mercury in particular.

Antoine Charles Lorry, the founder of French dermatology, drew attention to eruptions from various aromatic medicines, sudorifics, essential oils, etc (Tractatus de Morbis Cutaneis—Paris, 1777). Eruptions from other drugs began to receive notice. Montegre (1814) called attention to the appearance of urticaria following the ingestion of copaiba. Rayer (1835) recorded

numerous observations relating more particularly to the eruptive disorders caused by external irritants, which were classed by him as "artificial eruptions." Ricord (1842) described various skin lesions following the use of potassium iodide. Devergie (1857) first reported the skin disturbances caused by arsenic. Bazin (1862) devoted an entire monograph to the systematic studies of the cutaneous disorders provoked by the action of various drugs. He was followed by numerous observers, more particularly Berenguier (1874) and Deschamps (1878) in France, Kobner (1877), Lewin and Behrend (1879) in Germany, Farquharson and Hutchinson (1879) in England, Piffard (1881), Van Harlingen (1880), Morrow (1887), and others in this country, that added materially to our knowledge of the characteristics of such dermatoses.

Kobner¹ in 1877, in his clinical investigations of medicinal eruptions contended that those eruptions produced through internal use of a drug had a different pathogenesis than those produced through external application. Dermatologists of the same and next generation like Albert Neisser, Prince A. Morrow, Josef Jadasohn, Jean Darier, and others, believed there should be no such distinction, because it was not uncommonly noted that eruptions produced from contact with irritant drugs and those produced from the internal use of drugs were very frequently indistinguishable or merged with one another. Kobner's conception has been abandoned but the term "dermatitis venenata" is still applied to those dermatoses produced from external use of a remedy, and "dermatitis medicamentosa" to those eruptions produced from internal use of such preparations. While these divisions still have their usefulness at

Read at the Annual Meeting of the Medical Society of the State of New York, New York City April 28, 1936

he suggested, "should be limited to those processes wherein the introduction of foreign substances into the organism does not produce any clinical reaction whatever, where, in short, there is a total lack of sensitivity," the term "allergie" for the "altered condition which an organism achieves after acquaintance (Bekanntschaft) with any organic, living or inanimate poison," in other words, where specific hypersensitivity or hyposensitivity and immunity develops. Those vaccinated against smallpox, those tuberculous, and those who had received a serum injection, etc., said v Pirquet, were "allergic" to the respective foreign agent. He termed a foreign substance that is capable, through one or more exposures, of inducing in the organism this alteration of reaction as an "allergen." *Allergens include in addition to the antigens, numerous protein substances which do not produce antibodies but do cause hypersensitivity,* and v. Pirquet enumerated the following that may act as allergens—various infectious agents to which immunity may be established, poisons of mosquitoes and bee stings (where hyper- and hypo-sensitivity may exist), pollen that produces hay fever, urticariogenic substances in strawberries and crabs, and possibly, also, a number of other organic substances to which idiosyncrasy may appear.¹⁰

Allergy apparently covers a wide range of varied manifestations appearing in both animal and man, that are dependent on a specific alteration of capacity to react (hypersensitivity and hyposensitivity), induced in the organism by adequate contact with a definite substance or agent, even a harmless one. Sensitization is indicated in the presence of the following phenomena

A certain period of incubation (exposure to the agent) during which sensitization develops, this period (reaction time) is shortened with subsequent use of the specific agent, the presence of hypersensitivity or hyposensitivity (desensitization), no relationship of the symptoms of reaction to the nature of the agent, the capability of the offending agent even in minute amounts of reproducing the reaction, and its specificity for that particular agent, or those related (grouped), and occasionally to unrelated substances

The criteria for allergic hypersensitivity just mentioned, according to Doerr,¹¹ Bloch,¹² and others, also include the presence of responsible antibodies. According to v Pirquet's definition, the absence of responsible antibodies does not necessarily exclude the phenomena of specific sensitization from being allergic. Specific sensitization in animals and man is considered a cellular response, and the symptoms are attributed to a union of the circulating allergen with the tissue that had become sensitized.

There is some difference of opinion among immunologists as to the classification of the specific hypersensitivities, i.e., whether anaphylaxis rather than allergy is more suitable as a basic term for such manifestations. An internationally accepted definition of terms and also classifications of this subject, if it were possible, would be welcomed by many. It would be of help also in determining the value of new terms, like the more recent pathergy, metallergy, parallergy, etc.

v Pirquet's conception of allergy does not always postulate the necessary presence of responsible antibodies, so when they are not demonstrable in instances of specific sensitization, they need not be theoretically designated as "fixed" in the tissues, in order to account for their absence. For this reason, and others stated under the various captions that follow, the various specifically acquired hypersensitivities are classed under the general term "allergy."

Various Forms of Allergy

Anaphylaxis Protein anaphylaxis is a form of allergy (specific altered reaction) deliberately produced in laboratory animals, and characterized by a definite train of symptoms varying with the species employed. The presence of certain specific antibodies (precipitins) is regularly demonstrable. This type is also believed by some to be encountered occasionally in man in those sensitized to foreign serum or other proteins.

Atopy One form of human allergy is recognized by Cooke, Coca, and others, in those who have been shown to inherit a disposition to a certain type of sensitization. The individuals so disposed have been designated by Coca as "atopic." They have not been proven to show any greater tendency to develop drug eruptions than those not so constituted, but are subject

conceives it to be, mostly on clinical evidence and epidemicity, a "biotropic" effect, i.e., an activation of latent micro-organisms by such preparations. It is quite evident therefore that several factors may be at play in some types of drug eruptions.

There are, however, a large number of drug eruptions that are primarily either erythematous, urticarial or eczematous in nature, with minor differences when located on the orificial mucous membranes, or the appendages of the skin. Idiosyncrasy has been invoked as an explanation for the eruptions in this category, as well as the other less common types (lichen planus, herpes simplex and zoster, bromide and iodide nodular, and granulomatous lesions, etc.). The development of the idiosyncrasy in such instances is ascribed to a sensitizing and not to a poisonous* action of the drug. Practically any drug is capable of inducing sensitization. It has been found that some drugs are more apt to induce sensitization than others, and that it is possible for different lots of the same drug to vary in the frequency with which they may induce sensitization.⁹

General and specific Hypersensitivity

Progress in the understanding of idiosyncrasy as used in connection with drug eruptions and eczematous dermatitis, developed when it was indicated that some form of hypersensitivity existed in individuals so affected. Further experimental and clinical studies (Jadassohn, Bloch, Jaeger, Sulzberger, and others) revealed that there were certain differences in the types of hypersensitivity encountered. On the one hand there was the so-called normal individual who developed no reaction of the skin with various irritants (acids, alkalis, caustics, etc.), unless these irritants reached a certain concentration. These normal individuals would then manifest certain effects on the skin that were common to all, usually a dermatitis, with perhaps some slight variation in degree. Another group existed, the eczematous or potentially eczematous, in which a lower concentration of these same irritants could produce the same or even

a more severe type of dermatitis than that observed in the normal persons. These were hypersensitive in comparison with those previously mentioned. A subdivision of this general hypersensitive group would be those who reacted specifically to one irritant and not to others. General hypersensitivity may be encountered in those with a skin of a thin texture, or in those whose skin is exceedingly dry, etc. Specific hypersensitivity of the skin may be encountered in those susceptible to any particular irritant, (acids, alkalis, caustics, etc.), or in those susceptible to any physical agent like light, heat, cold, mechanical irritation, and may be due to some inherent biologic abnormality of the individual (difference in H⁺ ion concentration, presence of photosensitizing agents, or endocrine dysfunction, etc. respectively). This hypersensitivity even when specific, may or may not be of immunologic significance and in many instances is certainly nonimmunologic.

Such nonimmunologic hypersensitivity is to be contrasted with another type in which the skin of the individual has been known to react in a normal way to an agent (usually of a nonirritating nature) which has been used externally or internally, and then, due to a preceding exposure either proven or hypothetical, the skin acquires a new attribute in that he can no longer tolerate this particular substance thereafter, without the development of some cutaneous reaction. It has been shown to be possible to bring about this increase in sensitivity of the skin in this type of specific hypersensitivity through definite and repeated exposures of the skin to a specific agent. This production of hypersensitivity is therefore patterned after the specific immunological processes noted in experimental anaphylaxis and in certain other affections in which a specific acquired hypersensitivity is demonstrated.

Von Pirquet's Definition of Allergy

Von Pirquet's definition of allergy was based on the observations that those processes in which preparatory treatment induced immunity to various agents, were at times, also most intimately connected ("aufs Innigste mit einander verbunden sein") with an apparently contradictory phenomenon, the presence of hypersensitivity. "The designation 'immunity,'"

* The word "poisonous" is used throughout this paper in a restricted toxicological sense.

Sensitization to Drugs and Passive Transfer of Hypersensitivity

Swift¹⁹ reported sensitization with general symptoms in guinea pigs treated with arsphenamine guinea pig serum Frei²⁰ and Sulzberger²¹ have succeeded in producing skin lesions in man and guinea pigs through sensitization with neoarsphenamine. Active sensitization was produced in guinea pigs with phenylhydrazine by W. Jadassohn²². Landsteiner and Jacobs²³ produced cutaneous sensitization in guinea pigs with various chemical organic compounds (chloro dinitrobenzene and trinitrobenzene) but, other compounds similar in structure gave negative results.

The specific hypersensitivity of the epidermis in the eczematous type of drug eruption in man may be demonstrated frequently with the patch tests. In the other types, the scratch and intracutaneous tests are not reliable. Specific antibodies are not as a rule demonstrable. Passive transfer reagins (Prausnitz-Kustner antibodies) are reported only in isolated and doubtful instances.²⁴

Artificial sensitization in man to drugs applied externally has been reported by several investigators. Silverberg with mesotan (methoxymethylester of salicylic acid), Schwartzschild with the orthoform series, Lehner and Rajka with mustard oil and cignolin benzol, Biberstein with sodium nirvanol, and Nathan and Munk with a brand of arsphenamine. Biberstein succeeded in deliberately sensitizing the skin of an individual to mercury. These reports are cited in the article by Silverberg.²⁵ Bernstein²⁶ also succeeded in sensitizing man to formalin. Bloch¹² with primrose, and Müller and Mayer²⁷ with paraphenylenediamine (ursol), were successful in inducing sensitization in all individuals in which this was tried. Strauss²⁸ succeeded in causing sensitization of infants to poison ivy. Sulzberger²⁹ produced this hypersensitivity experimentally in an adult. The "nirvanol" (phenyl ethyl hydantoin) sickness³⁰ and its accompanying skin eruption, that is purposely induced for the treatment of chorea, is an example of an artificially produced drug eruption in humans, from internal use. Clinically, sensitization to drugs may de-

velop either from external or internal use and hypersensitivity may subsequently manifest itself with either method of administration.⁶ Jadassohn's demonstration was the first to prove the specific hypersensitivity to inorganic drugs like mercury, so that some inorganic preparations may also act as allergins.

Natural desensitization to a drug is not infrequently observed, especially after a severe outbreak. Artificial desensitization by employing the offending drug externally or internally, has been effective in some instances. Kesten and Laszlo³¹ reported a dermatitis due to external use of potassium mercuric iodide. Successful desensitization followed from the local applications of this preparation in gradually ascending concentrations. Desensitization in this way, however, is not always of a lasting nature. J. Jadassohn¹ showed that it was possible to accustom patients hypersensitive to the external use of mercury ointment, through gradually ascending doses of mercury by mouth or by injection. Widal and Pasteur Vallery-Radot³² protected a woman subject to a recurrent "fixed" erythema from antipyrine, from further attacks, by having the patient ingest at intervals of a few days, a small ascending dose of the drug by mouth one hour before the offending dose was administered. This was confirmed by Labbé and Haguenau³³ in an instance of a generalized antipyrine rash. These authors noted a drop in the leukopenic index soon after the offending dose. The other symptoms of a colloidoclasia (drop in blood pressure, disturbance in coagulation) were present in Widal's case. Urbach³⁴ caused desensitization to sodium cacodylate using the percutaneous method. Specific desensitization in Rhus dermatitis, against iodides, chrysarobin, and other drugs has proven useful. Specific and nonspecific desensitization and prevention of sensitization to the arsphenamines is based on the conception of an allergic hypersensitivity of drug reactions. Prevention of sensitization in the guinea pig to neoarsphenamine is indicated by the experiments of Sulzberger.²¹

Idiosyncrasy, Allergy, and Poisonous Action

The term idiosyncrasy is restricted by

to certain forms of asthma, hay fever, atopic dermatitis (infantile eczema, neurodermatitis), etc and occasionally react (asthma, hay fever) to certain foods, serums, and drugs in this way. Antibodies are demonstrable by means of the passive transfer experiments (Prausnitz-Küstner antibodies, also called "atopic reagins" or "atopens"). The nature of these antibodies and their causal connection with atopic affections need further elaboration.

Drug allergy The other form of allergy that may appear in man is acquired after an adequate exposure to a specific agent, usually without a familial history of atopy and without its antibodies. It is considered the type encountered in some of the foods, serum, bacteria, fungi, and drug hypersensitivities, and perhaps also in some of the hypersensitivities to physical agents. Cutaneous reactions are a common occurrence in this type, and the mechanism of sensitization is probably analagous to other types of allergy, although antibodies are not regularly demonstrable by present methods (Antibodies are sometimes demonstrated in some of the food sensitizations and serum sickness).

Experimental and Clinical Evidence of Allergic Nature of Drug Hypersensitivity

A drug may be well-tolerated for weeks, months or even years when for some reason the individual becomes receptive to the sensitizing action of the drug. From observations on those who have been exposed to the drug probably for the first time, the time required for sensitization of the skin to become manifest (appearance of skin eruption), is usually about one to two weeks. This period of incubation has striking similarities with that of other sensitizations, for instance in serum disease, nirvanol sickness, and in experimental drug and plant sensitization in animals. After skin sensitization is established, the subsequent use of the drug causes the skin eruption to reappear much earlier, i.e., within forty-eight hours. Skin eruption may be expected to recur thereafter with the use of the particular drug (specific reaction), or sometimes with those chemically related (group reactions), or even unrelated substances (heterophilic reactions?). The cutaneous manifestations that may appear usually differ from those produced by the phar-

macological action of the drug, and they can generally be reproduced by doses below the usually effective pharmacological dose. Similarly, the skin manifestations usually differ from those produced by the poisonous action of the drug. Relief generally follows by avoiding the offending drug. Desensitization may develop or at times be produced artificially. The reaction is not entirely dependent on the nature of the agent. The reaction is considered a cellular one in which the circulating drug (allergen) reproduces the drug eruption by a union with the skin or other tissue which has become specifically sensitized.¹³⁻¹⁶ There are as yet no known or regularly demonstrable antibodies.

Schuck, Doerr, Landsteiner, Zinsser, and other eminent authorities believe that although an antigen-antibody mechanism is far from proven in drug hypersensitivity, no other explanation is possible. The experiments with chemically-treated proteins by Obermayer and Pick, Landsteiner, and also Wells, supported this assumption. Landsteiner and van der Scheer¹⁷ have shown that anaphylactic shock may be induced in animals sensitized with azoproteins by injecting them with azodyes containing the same azo components as the sensitizing antigen. Other experiments of this order show it is possible at times to demonstrate specific antibodies to the chemical component (haptene) of the whole antigen used in producing the sensitization in the experimental animal. Simple chemical compounds under certain conditions act sometimes similarly to antigenic proteins. The relationship between specificity and the chemical constitution of chemical drugs offers a promising field for the solution of the phenomenon of hypersensitivity.¹⁸

While an antigen-antibody concept in drug eruptions is probably correct, it does not detract from v Pirquet's precise definition of allergy, for the latter adequately covers the class of specific hypersensitivities where specific antibodies cannot be demonstrated. Not only that, but this definition also limits the placing of other manifestations at the door of allergy, which are not based on v Pirquet's delineation of a specific altered reaction.

of drugs, much space is naturally devoted to their pharmacological action and also to their toxic (poisonous) effects. In recent years, attention is being paid to the sensitizing properties of these medicinal agents, for aside from deleterious effects resulting from an overdose of a poisonous drug, much that is considered toxic may be due to an underlying allergic hypersensitivity.

It is due mainly to the work of dermatologists like J. Jadassohn, Bloch, and their school, and various American and European immunologists, that the term *idiosyncrasy* formerly used to cloak our ignorance regarding the pathogenesis of drug eruptions, now receives a rational explanation. This is not only of theoretical importance but also of practical usefulness. It is perhaps confusing that the terminology and definitions employed to denote these phenomena are not altogether uniform. Further studies, it is hoped, will correct this. Sulzberger, through his many publications, is to be given credit for having emphasized the importance of this subject to American dermatologists.

Summary and Conclusions

The term "drug eruption" may be accepted as a general term for those eruptions due to external use (*dermatitis venenata*) as well as those from internal administration (*dermatitis medicamentosa*), of a medicinal substance.

J. Jadassohn's studies showed the relationship between drug eruptions and *eczematous dermatitis*, and revealed that *idiosyncrasy* in both of these skin affections is frequently based on an immunological type of a specific hypersensitivity to the offending agent.

The term "allergy" expresses according to v. Pirquet, the state of altered capacity to react (hypersensitivity and hyposensitivity) which occurs in the immunized organism, from contact with an allergen, i.e., an organic living or inanimate poison (or even a harmless substance).

The site of reaction of hypersensitivity is believed to be due to the union of the circulating allergen with the particular tissue sensitized.

The absence of responsible antibodies does not necessarily exclude the phe-

nomena of specific sensitization from being allergic.

Drugs in addition to their pharmacological and possible toxic action, also possess potential sensitizing properties.

A drug may act as an allergen, for it may induce sensitization. Sensitization of the skin develops during a definite incubation period. After skin sensitization is manifest, the reaction time is shorter with subsequent use of the drug. Desensitization occurs sometimes naturally and on occasions may be induced artificially.

A drug eruption is generally not in the nature of the pharmacologic action of the medicinal substance. The dose necessary to produce such symptoms is often below that required for the pharmacological effect of the drug. The eruption generally reappears with the use of the particular drug (specific reaction) or those closely related (group reaction), and sometimes unrelated substances. Relief generally follows the withdrawal of the responsible agent.

These manifestations are closely patterned after those appearing from a specific hypersensitivity to other substances (certain foods, serum, bacteria, fungi, and possibly physical agents), all of which are capable of inducing an allergic type of hypersensitivity.

This concept applies to a large group of drug eruptions that are primarily *erythematous*, *urticarial* or *eczematous* in nature, and may be the underlying basis also in those of different morphological appearance.

Drug allergy is considered a type of specific hypersensitivity encountered in man, that is often demonstrated to be acquired. Responsible antibodies are difficult to prove.

The inherited tendency to sensitization seen in other affections—certain forms of asthma, hay fever, atopic dermatitis, etc.—is considered the atopic type of allergy. Antibodies (Prausnitz-Kustner) are generally demonstrable.

Anaphylaxis is the classical form of allergic hypersensitivity produced in laboratory animals in which demonstrable antibodies are regularly present.

Of the hypotheses submitted as an explanation for the *idiosyncrasy* to drugs, it may be stated that the present evidence, while not complete, sustains the concept

some to those instances in which the hypersensitivity to drugs (cutaneous reaction) developed with the very first dose of the drug taken. Such instances of specific hypersensitivity are now generally believed to be, although it is difficult to prove, examples of an unapparent previous exposure (perhaps in utero) to the same or immunologically related substance. Usually, the hypersensitivity to drugs appears after the medicinal substance has been in use for a time. This has led to the explanation that such reactions are due to cumulative effects, and because some drugs are stored up in the body, cumulation also explained the reaction that reappears with renewed use of the drug after it has been omitted for many years. Meyer and Gotthieb, however, state that the storing of many powerful drugs in the liver, kidneys, bone marrow, etc., may occur to a considerable degree, without the least injury or change in their function.²⁶ Therefore, an allergic investigation of a drug reaction is always in order, irrespective of the demonstration of a quantitative increase of the drug in the individual.

Factors Determining Morphology of Drug Eruptions

Why the same drug will produce an erythematous or urticarial reaction in one patient and an eczematous eruption in another, and why the different drugs may produce the same type of reactions in various individuals, is dependent on other possible factors. Certain drugs, like arsenic and mercury, when applied in rather concentrated amounts as when used externally, may produce a dermatitis of an eczematous nature (epidermal effects). These same drugs when given internally, where the amount of the circulating drug is in a highly diluted form, may only affect the vascular structure of the cutis and give rise to the urticarial or erythematous lesions. It is believed by Josef Jadassohn that the question of whether the patient will respond with an eczematous type of reaction or another, is also dependent on the eczematous disposition of certain individuals. It may be also possible that the erythematous eruption represents one stage, a mild effect, which if it progresses further, will

finally result in the production of the usual eczematous dermatitis, for in some instances the eruption that appears may be erythematous or urticarial in certain areas of the skin and in other places of the same patient it may assume an eczematous appearance. This may be due also to some anatomical differences of various areas of the cutaneous surface. This is suggested, for example, by the observation that in the "fixed" eruptions (from antipyrine and its compounds, barbiturates, phenolphthalein, etc.), an erythematous patch may develop on the skin of the trunk with bullous lesions in the mouth and eczematous lesions on the genitals. On the other hand, certain drugs like cinchophen seem especially apt to cause a generalized urticaria,²⁸ other drugs the "fixed" eruptions, etc. Such characteristic features of drugs are of considerable help in detecting the drug responsible for the eruption.

Comments

The theory that most drug eruptions are an immunobiological phenomenon may be accepted on the evidence thus far advanced and until definite proof to the contrary shows it to be otherwise. Its mechanism as indicated by clinical and experimental studies point to the fulfillment of many postulates for a specific altered reaction capacity of the organism, i.e., allergy. An antigen-(hypothetical) antibody mechanism is assumed by some to show the close relationship of this type of allergy to another type—anaphylaxis.

Why the allergic phenomena, particularly as noted in drug eruptions, develop in some and not in others still remains a mystery. Luethlen suggested that it may be due to a colloidal disturbance. Others believe that it is based on changes in the H⁺ ion concentration in the organism. Various metabolic abnormalities, the liberation of histamine-like split products, endocrine influences, imbalance of the vegetative nervous system, intercurrent infections, previous injuries to the skin produced by various agents (x-rays, etc.), climatic differences, vitamin deficiencies, and other theories have been suggested, but experimental proof of any of these is difficult.

In the medical literature on the action

CONSERVATIVE TREATMENT OF THE NASAL SINUSES

HAROLD HAYS, M D, F A C S, *New York City*

I am well aware of the intense criticism which may greet my opening remarks and also that many rhinologists will disagree with some of my conclusions. However, there is only one way to drive home disagreeable facts and that is by talking plainly.

Quite a few years ago I wrote an article for the Gorgas Memorial Institute which was syndicated in many newspapers. It was entitled "The Sinus Bugaboo" and went on to state that perhaps more harm had been done by doctors and people knowing about sinuses than if they knew nothing about sinuses at all. I also stated that in the good old days, dirty, sniffing noses were cured by Dover's Powder and a good hot whiskey toddy. It is questionable to my mind whether people were worse off then than they are now. It would seem to me that physicians very often have frightened the wits out of people so that every time they have a cold they think they have a serious sinus condition which will need radical treatment. Most often a great many of the rhinologists view every cold in the head as a sinus condition and open up and wash out thousands of antra which would evacuate themselves with a very simple form of treatment or no treatment at all. I have frequently heard rhinologists say that hardly a day goes by without having two or three patients with sinus infections which need puncturing and irrigation. In our own practice, although we see many sinus cases every day, hardly once in six months is it necessary for us to open up a sinus surgically. I regret to say that thousands of sinuses are unnecessarily operated upon. It is indeed unfortunate that so many rhinologists examine sinuses with the idea in view that an operation is necessary. Patients have become so frightened at the word "sinus" that they immediately diminish their own resistance by worrying until in some cases they actually develop a serious condition.

The final conclusion to these remarks is that far too many antra are punctured and washed out unnecessarily, far too many sinus operations are performed either for acute, subacute or chronic conditions. I do not wish to put myself on a pedestal as the final arbiter in these conditions but I do wish to impress the profession with the fact that the conscientious rhinologist can cure ninety-nine per cent of so-called sinus conditions by conservative methods.

Within the past few weeks, one of the greatest physicians in this city died of an acute meningitis following an influenza. Years ago he had had an operation on his ethmoid cells. The infection crept through the granulation tissues in this region which had involved the cribriform plate. I have had two such disasters in my own practice. I had operated upon one of these cases myself. A second class of disabled patients are those who complain of severe frontal headaches which are usually due to a gastrointestinal toxemia. I was called upon to see such a patient in Los Angeles some years ago who died of meningitis after a radical frontal sinus operation when there was no doubt in my mind that an operation was entirely unnecessary. Further, I know of two patients who just avoided operation, one with meningeal symptoms who recovered by proper attention being paid to the intestinal tract.

By far the worse injustices are perpetrated on patients who show a clouding of one or both antra, either on transillumination or by x-ray pictures. Sometimes a fluid level is present. The roentgenologist frequently makes a statement that the antra and ethmoid cells contain granulations or pus. In my examination of thousands of x-ray reports and pictures, I find that in almost every instance there is evidence of such a condition, particularly in a large city like New York where the inclement winter weather will bring

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City April 28, 1936*

that drugs (organic or inorganic) may act as sensitizing agents, causing a specific allergic hypersensitivity of the organism. In the case of most drug reactions, this altered state manifests itself very often

in the skin, its appendages, and in the orificial mucous membranes, in the form of an eruption

Discussion

DR HOWARD FOX, *New York City*—Dr Abramowitz has discussed the allergic nature of drug eruptions in his usual careful and clear manner. He has given, I think, satisfactory evidence that the so-called idiosyncrasy to drugs is due to an acquired specific sensitivity whether the drug in question is organic or inorganic in nature.

We are glad to admit that the allergic conception of many disease processes has been of great value. As practicing dermatologists, however, we are not only interested in the nature of disease but want practical assistance in the diagnosis and treatment of our patients. In the case of drug eruptions the diagnosis is usually based on a history of taking a drug, on the disappearance of the eruption after discontinuance of the drug, and on its reappearance or accentuation when the drug is again taken. It was due to the last mentioned fact that Dr Abramowitz first proved that phenolphthalein could produce an eruption. I share a certain amount of credit in having reported the same original case (independently of Dr Abramowitz) but he deserves the chief credit in having proved his point by administering the drug again and causing a flare-up of the eruption.

It is unfortunate that cutaneous tests are of so little value in proving sensitization to drugs, with the exception of some unusual cases of eczematous type where patch tests are of assistance. It is also unfortunate that skin tests do not show as a rule, whether the administration of arsenamine (or allied drugs) will be well-tolerated or whether it will be followed by ill effects.

In sensitization due to certain drugs such as iodides and bromides, it should not be forgotten that the eruption may persist for weeks, months or even a year or so after administration of the drug has been discontinued.

One reason for skepticism or even hostility to the allergic study of skin diseases in general is due to the tendency to lay too much stress on the value of skin tests in unsuitable cases. I refer especially to the use of scratch and intradermic tests in contact dermatitis where patch tests are indicated. We are beginning to realize that the patient's history is usually much more important than skin tests though all too frequently this fails to help us. The indiscriminate use of skin tests causes a great waste of time and money and adds unnecessarily to the cost of medical care.

The mother is also advised to have the child wear a light woolen sleeping suit at night and to see that the patient does not sleep in a room with too much cold air. The mother is also instructed to instill a mild alkaline solution into the nose, night and morning, by means of a

medicine dropper. The result was truly miraculous. In these patients there was an improvement within forty-eight hours and today both patients have gained in weight and the sinus infection has disappeared.

Other cases, of course, are not so simple. Some children must go to a warmer climate if possible. And, in all cases the parents should be told that each winter the same symptoms may appear until the child reaches puberty.

the course of a year hardly a day goes by that we do not see a number of such cases. The type of treatment which is given will depend upon the case, but it is rarely necessary to advise operation on any of these patients. We have a variety of adjuvant treatments, but the general routine is about the same—increasing resistance and cleaning out the sinuses with a suction douche apparatus which will be described later. It is self-evident that if a definite pathology is

about a pathology in the ethmoid cells. Such a picture will not be present when summer comes on or when the patient's general physical condition has improved. About ten years ago, I suffered considerably from a congested nose and a post-nasal drip. X-ray pictures showed both antra filled with granulations and possible polyp. It was suggested that I have a radical antrum operation performed which I refused to have done. A few years later, when I was feeling better I had some more pictures taken. The sinuses were perfectly clear. Quite some years ago, a patient came in to see me complaining of a gnawing pain on the right side of the face. The x-ray pictures showed definite evidence of pathology in the right antrum—possibly a malignant growth. A radical operation was agreed upon and this advice was corroborated by another rhinologist. The patient decided to wait over the summer, during which time I could watch him. In the fall, he agreed to have the operation performed. We had another x-ray picture taken because the pain had disappeared and the patient looked perfectly well. A comparison of the two films showed that the growth had entirely disappeared. With these experiences and with attendance on thousands of patients with nasal complaints in over twenty-five years of specialized practice, I believe I am in a position to state that the majority of suspected sinus conditions should not be operated upon and that almost without exception the majority of these affections will recover if treated conservatively.

It is unnecessary to go into a detailed classification of sinus diseases. It is also unnecessary to do more than state that there are certain sinus affections which have to be treated radically. For our purposes the patients divide themselves into children and adults, into acute and chronic cases.

Acute Sinusitis in Children

Infrequently we come upon cases where acute symptoms are present so that immediate operation is imperative. The main symptoms are severe pain in the face or headache, rapid swelling of the tissues, often with closure of the

eyes, high temperature, and sometimes delirium or coma. These cases are rare.

By far the majority of these little patients have continual and repeated colds often without temperature and present a physical condition below par. Some still have tonsils and adenoids, others have had them removed, and still others show an edematous condition of the nasopharynx sometimes with remnants of adenoids still present. We shall take it for granted that if tonsils and adenoids are evident that advice is given for their removal.

Local physical examination of these patients will show an engorgement or edema of the mucosa of the nose, and there may or may not be pus or mucopus in the nasal cavities. Examination of the throat shows a definite nasal drip. Transillumination may show one or both antra cloudy but good drainage may be determined to be taking place because one can see the retina plainly. General physical examination frequently reveals that the child is below par physically. The x-ray pictures may show that both antra and ethmoid cells are cloudy.

Two such little patients came to my office within the past few months. In both cases (the tonsils and adenoids having been removed) radical operation on the antra and ethmoid cells had been advised by competent rhinologists.

In order to see what can be done in such cases, let us review the course of treatment in these patients. First of all it was evident that these children were suffering from no pain and were not running temperatures. Secondly it was evident that if the resistance of these patients could be improved, they would get well without operation. The engorged mucosa was shrunk with a mild solution of cocaine and ephedrine by placing a cotton tampon immersed in this solution in the nose. The patient was placed in front of an infra-red lamp for ten to fifteen minutes and then the nasal cavities were thoroughly washed out with a mild alkaline solution followed by an oil spray. But the next important thing was to build up the general system and nothing works better than the administration of a combination of vitamins A and D. It matters not what preparation is used.

The mother is also advised to have the child wear a light woolen sleeping suit at night and to see that the patient does not sleep in a room with too much cold air. The mother is also instructed to instill a mild alkaline solution into the nose, night and morning, by means of a

the upper jaw on the left side. It was removed and the pain disappeared.

The conservative treatment of so-called chronic sinus conditions is of even more importance. One must look at these patients from two angles and two questions must be asked. *First*, is the patient going to be relieved of his local

of affairs which will take place after the patient has been operated upon. Again, one must consider whether diseased conditions in other parts of the body may or may not be responsible. For example, a few years ago a patient was brought to me who was suffering from a persistent cough with loss of

Fig 2 X-ray of antra, showing right antrum filled with pus
(X-rays from the files of Dr Herman B Philips)

Fig 3 X-ray of antra taken four days later, after use of Suction Douche three times. A large amount of pus was washed out of the antrum each time.

symptoms by radical operative procedures? *Second*, is the patient going to be relieved of general symptoms by operation? For example, how many cases of asthma have been relieved in whole or in part by operation on the sinuses?

One may make one absolute statement about the majority of these patients. If they continue to live in the same atmosphere, go on with the same work, always suffer the same indignity to their nasal membranes, continue to worry, never take any exercise during the winter months, they will always suffer from nasal and sinus symptoms whether they have any operation or not. In determining whether they need more than conservative treatment, one must take every fact into consideration, weigh the pros and cons and determine the actual state

weight. He looked sick. Some pathology was found in his right antrum and a radical operation advised. I advised against it but it was performed anyway. The patient died of a carcinoma of the lung some few months later.

The routine treatment of chronic cases is similar to that already outlined. Sometimes we attempt to create more osmosis by tamponing the nose. Our main advice to the patient is to have him go to a more agreeable climate if possible. If this cannot be done, we build up the general system as well as we can and tell the patient that operation seldom cures the condition, that palliative treatment will relieve them as much as anything. A good night's sleep helps a great deal so the patient is given a barbitol preparation and he is strenuously ad-

found in the nose, it must be attended to surgically, preferably at a time when there is a minimum infection of the mucosa. I refer mainly to a marked deviation of the septum, which interferes with drainage, hypertrophy of the middle turbinates or a polypoid condition of the mucosa in this area or large, polypoid tips of the inferior turbinates. Occasionally, a patient presents himself with a definite pathology in one or more of the sinuses which surgical intervention only can relieve, but these are relatively rare cases. What we object to most strenuously is the feeling on the part of many rhinologists that operations on the sinuses, of one kind or another, must be performed.

It is almost needless to say that the majority of acute sinus conditions will recover with a very simple treatment in the course of time, or with no treatment at all. Because an antrum appears cloudy is no reason for washing it out even when there is acute pain. Many times these cavities are washed out and no pus or mucopus found. The clouding is due to an inflamed mucosa and nothing else. The routine treatment in acute sinusitis in adults, whether it involves one antrum or all the sinuses is very simple. The patient's nasal mucous membranes are shrunk with a mild cocaine and ephedrine solution (as with children). The patient is placed in front of an infra-red lamp for fifteen to twenty minutes. If he has any pain at all, he is given a quarter grain of codeine and five grains of aspirin. Naturally the routine examination of the nose and throat is made, including transillumination. The pledgets of cotton are removed from the nose and another examination made for trouble that could not be seen before the membranes were shrunk. As a rule nothing serious is found. The nasal cavities are now washed out by a suction douche apparatus which I devised some years ago. The action of the shrinking solution has caused the loosening of the plugs in the natural openings so that they are easily removed by suction and the further suction is sufficient to rid the sinuses of infection for the time being at least. The suction apparatus consists of a T-shaped contrivance which connects permanently with the cold

water faucet. A tube goes from this to an indicator which records the amount of suction used. A second tube leads from a Valentine irrigation bottle which contains the washing solution. We use the old Harmon Smith formula. The amount of suction is registered on an indicator. The usual amount of suction is between five and fifteen pounds, when the water is turned on. To the nasal tubes are attached hard rubber tips which fit into the nostrils. First one side of the nose is washed out, the tips reversed and the other side washed out. If there is much pus in the first filled bottle, a second and a third bottle is used until the washings are clear. In the wash bottles one sees the plugs which closed the natural orifices and a considerable amount of pus or mucopus which has been drained out of the sinuses. Sometimes there is as much as an ounce or two. In nine cases out of ten, the patient is immediately relieved. After washing, the nose is thoroughly sprayed with some oily solution.

Inquiry is made about the patient's general physical condition and whether there is any trouble in the gastrointestinal tract. If the patient has to be built up physically he is given tonics, and routinely receives injections of one of the non-specific proteins. The patient is requested to return daily until the washings are clear. He is advised in the meantime to take a capsule containing two and one-half grains of aspirin, two and one-half grains of pyramidon, and one-eighth grain of codeine, three to four times a day. As a rule patients are cured in four to six treatments.

Other so-called acute sinus conditions are not so simple. At the beginning of this paper, I mentioned certain cases which were diagnosed as sinusitis and where the symptoms were caused by gastrointestinal toxemia. Recently a patient came to me who was complaining of a severe pain over his left eye which persisted night and day for over three months. The pain continued. Examination with x-rays showed no real sinus condition. His eyes were again examined and a weakness of the musculature of the left eye corrected. This was not enough. A buried wisdom tooth was found in

ected mucosa being in the nasal fossae proper, and not in the paranasal cells. It seems hardly likely that anybody would tear down the sinus walls in such a case.

However, diagnosis, accurate diagnosis of sinus disease, in spite of all mechanical aids is not uniformly satisfactory. Personally, I do not think much of transillumination save for its effect upon the mind of the patient, for thick bone on one side and thin on the other may lead to false conclusions. The only satisfactory x-ray pictures are the three-dimensional ones viewed stereoscopically. Where definite pathology exists, it will be shown exceedingly well the only disadvantage is the human tendency to try to read something into the interpretation which is false or of little importance. I have been tricked by pictures, but I still think that they are the very best means of making a thorough diagnosis of the size, shape, and extent of the sinuses, and determining variations from the normal. When a patient walks in at the first visit with a proud display of "pictures of the sinuses made by my own doctor," I begin immediately to plan what I shall say which will not make a liar out of me and a "monkey" out of the amateur roentgenologist. These single flat pictures are seldom of value. I would never think of operating upon a patient from a diagnosis determined by them. Even the best pictures are none too good.

Dr Hays is quite right when he decries the habit of washing out every antrum which seems to show a little cloudiness. Clinical evidence is a much better guide, for if there is little or no pus in the middle meatus or in the nasopharynx, an empyema of the antrum of Highmore is extremely unlikely. Moreover, I do not follow the practice which many excellent rhinologists do, of putting a needle through the naso-antral wall in an acute case, and giving daily irrigations for two or three weeks. If an antrum is that bad, it is much better to make a small permanent hole in the wall and wash through it as necessary. This does no harm, but it does permit of more or less constant drainage even in the absence of treatment. Irrigation through the normal opening is sometimes quite satisfactory, but this is entirely dependent upon the anatomy, whether there are two openings, or one large normal opening. The return flow may then quite readily pass out along side the catheter.

If any of us have forgotten our sinus pathology we must retrace our steps and spend a little time with Onodi or Hajek or Skillern or some other comprehensive authority. I believe that no sinus which

contains stinking pus, polyp or necrotic bone can be cured without radical surgery. This is especially true of the antrum and the frontal. Some of the most satisfied patients whom I have ever had, have recovered after such radical sinus surgery. Many of them had run the entire gamut of tampons and light therapy and visits to Arizona. This is especially true of the antrum cases. Radical antrotomy under block anesthesia can be quickly and skillfully done with destruction of nothing save a button of bone removed from the canine fossa and nasoantral wall. Removal of diseased antral contents is followed by nearly complete healing within two weeks during which time there should be a minimum of washing and spraying and general meddling. If we do a good operation, nature will often do the rest.

Radical surgery of the frontal is not so simple, but the results are nearly as good if we do not try to do too much in taking away normal bone and soft tissue. It so happens that never yet have I been obliged to remove the superciliary arch for necrosis. The deformity is very unsightly, and I have always doubted whether complete obliteration of the cavity is possible by any operative procedure, no matter by what label it is known.

Sinus surgery in children should be relegated to those patients with alarming symptoms or signs who seem likely to die if heroic measures are not adopted. Most children do surprisingly well with the conservative measures outlined by Dr Hays. What we need is more and better cooperation with the pediatricist. Working together we can get most of these little patients well without surgery. However, children with rheumatic fever should not be spared radical operations if we can feel reasonably sure that a focus of infection exists in the sinuses. More often, however, the nidus is in those little islands of infected lymphoid tissue which lie everywhere in the nasopharynx and on the posterior wall, even after thorough A and T removal.

Suction-irrigation is a helpful means of cleansing the nose, and it often gives relief from pain. Dr Hays' method of doing this seems admirable and entirely adequate. It cannot seriously be advocated as a "cure" for chronic sinusitis, however. We must always be mindful of pathology.

I am a little surprised that no mention is made in the paper of the Dowling Argyrol Pack. Personally, I have long since stopped using it, and I wonder if Dr Hays has also discontinued its use.

As to ephedrine, it is certainly no boon to the lary. They have gone to great ex-

vised against the constant use of adrenalin or ephedrine preparations

In closing this paper, again let me say that medicine has lost a great deal by treating patients empirically. Because it has seemed best to puncture antrum with trocar and cannula in certain specific cases is no reason why every antrum should be punctured. As a matter of fact, does washing out an antrum that way accomplish more than cleaning it out with a suction douche apparatus? Does washing out through the natural opening, with its attendant discomfort, do any more good? The mechanics are obvious. No one ever washed an antrum through a puncture opening. The fluid is forced through the antrum but comes out of the natural opening by pressure. So why not use the simpler procedure—the suction douche?

Conclusion

In conclusion let me emphasize the following points

1 The majority of sinus conditions, acute or chronic will respond to conservative treatment

2 Too many antra are opened and washed out

3 In many cases, operative procedures on the sinuses will not result in permanent benefit

4 Treating sinuses with the suction douche apparatus will cure many cases and be of material benefit in others

5 The majority of serious conditions result from a lowered body resistance. There can be no permanent improvement until the general system is brought up to par

Discussion

DR I W VOORHEES, *New York City*—Dr Hays and I are old friends, in fact we were graduated in the same class from the old P & S in 1905. Therefore, in what I have to say there will be no thought of "personality" or vindictiveness. I know that Hays is a good doctor, and that in this paper he has set down his honest opinions as a clinician. He is making no attempt to be "scientific," but wishes to be intensely practical. Nevertheless, is it not possible that in some of his assertions he is too sweeping, and that in some of his nonsurgical therapeutics he is too enthusiastic? He says, for example, that "many sinuses get well after all, any, or no treatment." May we not also say that many sinus cases die after all, any, or no treatment?

The old economic law works here just as it works elsewhere, namely that the *summum bonum* of all human endeavor is to achieve the greatest good for the greatest number. Dr Hays is trying to do this by nonsurgical treatment of sinusitis. This is a little surprising, for in his early years as a specialist, it sometimes seemed to me that he used to overwork his surgery a bit now and then. Has he reformed, been converted to anti-surgery, or just what has happened to him? I don't know the answer to that, but I do know that in what he said to us just now, he is aiming to be very honest, and to follow his conscience. That is a praiseworthy thing for any man to do.

To begin with, I think he is right in say-

ing that the fear complex is too much with our sinus patients. Possibly, we, as rhinologists, have been telling the patient too much or allowing him to get hold of information concerning sinus trouble which is not good for him. A similar thing happened when we talked too much about mastoiditis. Every person who had a pain within an inch of the ear immediately became panicky from a "mastoid complex" and had visions of compulsory surgery, and, in the words of the newspapers, "death from an operation." Either too much or too little of a certain kind of knowledge can become harmful to our happiness and peace of mind.

I was startled to hear that "the conscientious rhinologist can cure ninety-nine per cent of so-called sinus conditions by conservative methods." This would leave only one per cent of all cases to surgery. Just what per cent of rhinologists would be left who are *not* too conscientious is left to the imagination. I have a feeling that it would be very dreadful. This is obviously an overstatement, for I doubt whether any one of us can cure ninety-nine per cent of any disease, no matter what it is. The law of averages is always working, and this law will see to it that none of us is allowed to become too cock-sure either of his ability or good fortune. The saving word in Dr Hays' sentence is "so-called," and I am sure he was thinking of many patients with rhinitis who have no sinus complications, or at least only a minor involvement in the sinuses, most of the in-

RATIONALE OF THE TREATMENT OF URINARY INFECTIONS

DAVID M. DAVIS, M.D., *Philadelphia, Pa.*

Professor of Genito-Urinary Surgery, Jefferson Medical College

As I pondered the subject of this paper it occurred to me that its wording serves to call attention to the very real progress which has been made in this field.

Not so very long ago, there was very little in the treatment of urinary infections which could be called rational. Urinary infection meant bacteria in the urinary tract, therefore, the proper thing was to inject germicides into the urinary tract, much as if it were a slop pail or specimen bottle. Observing physicians did not fail to note that the results were usually quite unsatisfactory, and just as unsatisfactory whether the injections were made frequently or infrequently, or whether the germicide was weak or strong. These latter facts cast discredit on the entire theory of cure by direct chemical germicidal action, and today every writer on the subject puts local treatment with germicidal substances last in his list of therapeutic measures against urinary infection.

It would be interesting to trace the development of each of our modern points of view about infection, but lack of time forbids. Our profession is conservative and skeptical, and rightly so, but it is always anxious to adopt that which is of proved merit. It takes time, of course, for a new idea to penetrate to all the multitudinous units of such a huge group, but speaking as I am to urologists, I can take it for granted that in the treatment of urinary infections it has become entirely orthodox with them to consider, *first* the focus or portal of entry from which the infection has originated, *second* stasis of any kind or degree which may exist in the urinary tract, and *third*, metabolic conditions which may favor infection, and to investigate all three of these thoroughly before worrying about what particular medicament is to be used, locally or otherwise. This gives us a

right to speak of the rationale of treatment, and shows that we are at last approaching the time when we shall prescribe our remedies in this field precisely according to a precise knowledge of the etiological factors involved.

I conceive that it would be presumptuous on my part to rehearse in detail all of the therapeutic methods now in vogue or in the process of exploitation. I shall, therefore, confine my remarks to a few observations which I believe to be pertinent, and which I hope may be provocative.

While some of our dental colleagues have protested, properly enough, against the indiscriminate pulling of teeth, yet one of their number has shown that almost ten per cent of apical infections are not susceptible of demonstration by the x-ray. This finding sadly complicates the problem when devitalized teeth are present, and adds to the weight of the physician's responsibility. The decision for or against the removal of such teeth can only be made by the closest and most conscientious cooperation between dentist and urologist.

In the matter of focal infections pyorrhea should not be forgotten. If this disease is severe, and has undermined the gums deeply, it may flood the system with infectious material just as effectively as any periapical abscess, and in such advanced cases, exodontia may be the only effective remedy.

The search for infectious foci must be painstaking and determined. The dentist, the laryngologist, the otologist, the dermatologist, the gastroenterologist, the gynecologist, and the proctologist may all be called on to help, and much depends on the intelligence and conviction with which they perform their tasks.

When everything is done there will remain some unfortunates whose infect-

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City April 29, 1936*

trenies with it. In effect it is evanescent, has to be frequently repeated, and is likely to cause undesirable change in the mucosa and small blood vessels. However, in combination with other agents, it is useful in office treatments instead of adrenalin which gives, at times, an undesirable local reaction.

Regarding the patient with carcinoma of the lung who also had a bad antrum, the cause of cough and loss of weight should have been looked for in the lung and not in the antrum. Competent physical examination and an x-ray picture of the chest would have made the diagnosis. But, even so, radical antrum operation did not shorten the patient's life, for, often, there is less actual discomfort after a radical antrum than after a submucous.

Finally, conservative treatment of the nasal sinuses is to be recommended if one feels reasonably sure that surgery will not be demanded in the long run. If surgery must be done ultimately, then we have merely been wasting time and substance by nonsurgical treatment.

DR CHESTER C. COTT, *Buffalo*—Dr Hays' paper is full of good common sense. At the close he seems to limit conservative treatment to the use of his suction irrigation only. Various intranasal measures should be included in this term, such as washing out the antrum through the middle meatus, normal meatus or not as you wish, and to the drainage of the frontal sinus by means of fracture of the middle turbinate toward the septum, constricting the membranes at the frontal orifice with adrenalin and removing the pus by suction with a cannula. This is very mild treatment and, in my hands, has often cured the acute frontal sinusitis. I cannot see how a frontal sinus full of pus and held there by edematous tissue can be removed by Dr Hays' method. And washing out the antrum through the middle meatus has no "attendant discomfort" to which I personally can testify.

There is certainly too much faith put into the reading of x-ray films. They should be considered as only another aid in diagnosis. Acute sinuses should not be operated on except in cases of emergency. Chronic cases are those which contain polyp or pyogenic membranes in the sinuses and which have resisted our efforts to obtain a cure by conservative measures. The x-ray is helpful in giving us an idea of the contour and size of the sphenoid and frontal sinuses but should not be relied upon to make the diagnosis for us.

Dr Hays does not mention the use of the Holmes Electric Nasopharyngoscope for diagnosis. Every case should be examined with this instrument as it gives a perfectly clear and definite view of the posterior nares. If pus is there, it can be seen in the places characteristic for each group of sinuses. It has made our specialty much more of a science.

The infra-red lamp in my hands has given the patient a very comfortable feeling for a short time but apparently does no more good than a thorough adrenalinization of the nose and does not last any longer.

A warning is given against the "constant" use of adrenalin. I suppose office use or given as a spray or drops at home is meant. Recently a great deal of ephedrine has been sold over the counter. Still I have never seen any bad effect resulting from the use of it.

There certainly are some cases which will not improve regardless of the type of treatment or operation carried out if they remain in the same locality. Sometimes removing only a few miles away cures them—as long as they stay there.

Dr Hays may have the ideal conservative treatment here. My objections may be overcome in the future. At present I cannot see how it would empty the sinuses in certain cases. Still it would be much better to have this type of apparatus used to the exclusion of all other types of treatment if it would decrease the great amount of sinus surgery now being done.

At the annual meeting of the New York Academy of Medicine, held Dec. 3 at the Academy, 103d Street and Fifth Avenue, Dr. James Alexander Miller was elected president. Other officers chosen were Dr. Arthur F. Chace, vice president, and Dr. Lewis F. Frissell, recording secretary.

The retiring president, Dr. Eugene H. Pool, and Dr. Walter L. Niles were elected

to the board of trustees for five years.

Dr. James Grafton Rogers, master at Timothy Dwight College, Yale University, the guest speaker, discussed the problem of socialized or State medicine and advanced the opinion that the objectives sought by the supporters of State medicine were being attained by changes within the profession and practice of medicine itself.

not only the existence but also the prevalence—of mild and obscure forms of urinary obstruction is at the present moment one of my dearest personal hobbies, and I must therefore crave your indulgence for what I say about it

The extreme attitude would be that in any case in which urinary infection *persists* for a long time, one should *assume* that obstruction and stasis exist. On this assumption, the urologist would approach his task with the idea that he is facing the necessity of proving positively that there *is no* obstruction or stasis, rather than the usual idea that he is facing the necessity of proving to a moderately skeptical audience that there *is* obstruction or stasis. I do not advocate or recommend such an attitude, but I suggest it to urologists of an investigative turn of mind as a stimulus to the intensive search for mild and obscure obstructions. In my own work, this attitude has led me to believe that in any case where a ureteral narrowing comes in question, all three methods of investigation at our command—intravenous urogram, retrograde pyelo-ureterogram, and exploration with a bulb of proper size—should be used if there is the slightest doubt one way or the other. The final objective in each case must be, of course, the actual cure of an infection by suitable treatment directed toward the relief of the presumed obstruction.

Whether the obstruction is gross and unmistakable, or whether it is slight and perhaps somewhat doubtful, the treatment to be adopted must depend on the character of the obstruction. For example, systematic dilatation will cure most strictures of the urethra and of the lower segments of the ureters, but there are exceptions to this rule. Such exceptions are the extremely dense and firm strictures, which must be divided or excised, and congenital strictures of the urethral or ureteral meatus, which must be divided. On the other hand, strictures of the upper third of the ureters, congenital stenoses of the uretero-pelvic junction, or narrowings due to aberrant blood-vessels, bands of fascia or adhesions, can seldom be influenced by dilatation and must be treated surgically. Certain contractures of the vesical orifice can be successfully dilated, but median bar obstruc-

tions and dense fibrous contractures, whether congenital or acquired, must be treated surgically by some method which will remove the abnormal tissue and enlarge the vesical orifice to its normal size. In a word, the judgment of the keen and experienced urologist is invaluable because it will, in one case, save the patient from weeks and months of useless and irrational treatments, and, in another, from an unnecessary surgical operation.

Obstructions due to senile enlargement of the prostate need only to be mentioned, as they are usually obvious, and the proper treatment is known to everyone, but it is not so universally known that a chronic urinary infection often disappears after a prostatectomy, and this fact should be emphasized.

Before turning to medicinal and dietary methods of treatment, permit me to repeat urgently the plea that continuous efforts be made to impress upon the profession at large the paramount importance of urinary stasis in the causation and in the perpetuation of urinary infections, and that, if any infection persists more than three or four weeks, a complete and careful urological investigation should be carried out at once, instead of waiting for months and until everything else has failed. It should be remembered, also, that in the exceptional cases where medicinal or dietary treatment cures an infection in spite of an associated stasis—and this does happen sometimes—the patient still remains a prospective victim of the damage which will eventually result from the obstruction alone, even in the unlikely event that the infection never returns.

In ancient times, when the gullet was the royal road, through which passed practically all of the materials intended for the relief of human suffering, the popular remedies for bladder trouble were almost invariably in the nature of sedatives. Even in those days, however, the medicine which is still perhaps the best for urinary infections was in high favor. I refer to water. Except in certain circumstances, to be mentioned later, copious water drinking is the old reliable method for the cure of urinary infections, but its value is in direct proportion to the freedom with which the urine can be expelled from the body. Later, as I have

ious foci, while not escaping detection, are, from their very nature, practically incurable. Examples of this are severe chronic sinusitis, chronic pulmonary infections, especially bronchiectasis, and ulcerative colitis. In such cases, everyone concerned can only do his best.

The radical elimination of an active focus of infection may bring about complete and permanent cure of a urinary infection without the assistance of any local treatment whatever. Such an event furnishes rather weighty presumptive evidence that the urinary tract is anatomically and functionally normal. If, on the contrary, the urinary infection persists, with or without the eradication of a definite portal of entry, the wise physician will suspect stasis in the urinary tract and will set about a thorough search for it, not neglecting evidences of slight urinary obstruction, of a degree which the uninitiated might think unimportant and negligible.

The relationship between urinary obstruction and infection is getting to be an old story, and is well incorporated in the gospel of most urologists. Like many another clear and sparkling fact, it stared us in the face for a long time before it was recognized, and much gratitude is due those pioneers whose common sense informed them that if free drainage through a rubber tube would relieve a pyonephrosis, free drainage through the ureter might do the same thing. At the present moment, however, there is danger that the rest of the profession may lose sight of this fundamental and very rational concept, and ignore it in their enthusiasm for the fascinating theories underlying the dietary and metabolic systems of attack on urinary infection. The onus of preserving a rational balance in what we might call the popular attitudes toward these complex matters falls on the urologists. Anyone may speculate on the intricacies of the acid-base metabolism, of the body, or may admire the rich golden-brown color of pyridium-tinted urine, but only the urologist can evaluate a slight ureteral constriction or a fibrous contracture of the vesical orifice. It must be impressed on the medical world that drugs, vaccines, and diets, valuable as they are, can, in the nature of things, be

of very little use as long as there is definite interference with the free and unimpeded drainage of urine from any part whatsoever of the urinary tract.

Stasis of urine may be due, not only to obstruction, but also to lack of expulsive power from affections of the nerves supplying the muscular coats of the bladder or ureters. Everyone is familiar with the utterly intractable character of infections occurring in such cases, unless and until the emptying power is restored. This kind of stasis may well be called adynamic stasis. It may or may not be amenable to treatment, but its most important aspect is that it is sometimes very difficult to diagnose. Aside from the various examinations which can be made to determine the state of the central and peripheral nervous systems, I can only remind you of the cystometric test, and urge that it be employed in every doubtful case. The information it gives is exact and reliable, and its application is simple. I have frequently performed it with no special apparatus. If the catheter be connected with a vertical piece of glass tubing about four feet long, the pressures can be read off directly in centimeters of water. Fluid is injected through a side tube between the catheter and the upright tube. This arrangement can be assembled in a few minutes in any hospital, and in most urologists' offices.

Obstructive stasis is much more common, of course, than adynamic stasis. We are naturally interested to know just how common it is in cases of urinary infection. Quinby, in an article published in 1934, estimated that stasis was present in possibly fifteen per cent of the cases of infection. I am sorry that I cannot furnish any definite figures on this point, because it is my emphatic conviction that the correct percentage is very much higher than fifteen percent. If this is true, it must mean that many cases of obstruction have slipped through our diagnostic drag-net in the past. Localized renal pain, an enlarged kidney, frequent and difficult urination—all point the finger unmistakably toward obstruction and stasis. When, however, these cardinal symptoms are slight or absent, obstruction and stasis may still be present. To attempt to prove the existence—indeed,

ide or nitrate. This throws us back at once to older observations concerning the reaction of urine in infections. Normal urine varies in reaction according to the diet, since some foods are much more acid-forming than others. It is commonly stated that colon bacilli and tubercle bacilli are found only in acid urine, yet if the pH of the urine is below five (that is, more acid than 5) colon bacilli will not grow in it. It is commonly stated that urine infected with cocci is usually alkaline, but clinical observation shows that this is not true, although there is some evidence that a urine of about pH 7.6 (7.4 being neutral) is more apt to be infected with staphylococci than with colon bacilli. Be that as it may, everyone knows that colon bacilli, staphylococci, and streptococci can flourish together in the same urine. For many years, the plan of making the urine alternately alkaline and acid has been widely used in the treatment of infections, and the indifferent results ascribed to the difficulty, by means of diet or medication, in getting it acid enough or alkaline enough. At any rate, a good many people jumped to the conclusion that the chief virtue, if not the only virtue, of the ketogenic diet was the high acidity of the urine produced, and attempted to produce the same acidity by other and simpler means. The most spectacular of these were suggested by Crance, who gave large doses of nitrohydrochloric acid (aqua regia) by mouth, and by Shropshire, who gave hydrochloric acid in 1:1500 dilution by intravenous injection. Both claim success, but neither method has been followed by enough others to qualify as a generally accepted method. One should, perhaps, mention in passing the highly successful method of treating infections of urinary wounds with bacillus proteus and other urea-splitting organisms by local applications of acetic or phosphoric acid.

Over against this is the statement of Fuller that the active bacteriostatic agent in the urine of patients on the ketogenic

diet is the levorotatory form of beta-oxybutyric acid, and the clinical observation of Cabot that the acidity produced by the ketogenic diet is more effective than an equal acidity produced by drugs.

Certainly, the wise clinician must believe that much of all this is still *sub-judice*, but on the other hand it appears that the nature of the problem is such that it should be susceptible of a reasonably early solution, particularly if attacked by competent biochemists. I suspect that sooner or later we shall have either the active principle of the ketoniferous urine in convenient tablet form,* or a simple and easy method of producing a highly acid urine. The ketogenic diet in its present form is too difficult to prepare, and too unpleasant to take to be a very practical therapeutic method.

As a by-product, we may obtain a better knowledge of some physiological points. The reaction of the normal urine varies from hour to hour through the day. As hydrochloric acid is secreted into the stomach, hydroxyl ions are excreted in the urine to preserve the neutrality of the blood, and the urine becomes alkaline. As the acid radicles are resorbed during digestion, the urine becomes acid again. In gastric anacidity, this acid-alkaline tide in the urine does not occur, and some observers think such individuals are more susceptible to urinary infection.

I leave this group of fragments of knowledge with you in the hope that they may intrigue you as they have me. The ketogenic diet is a fine contribution, but it is not the last word.

In conclusion, may I urge that we keep our minds eager and open for all that is good, however new, but that we remember the fundamental importance of urinary stasis, and keep our dilators and our scalpels in good working order, for there is nothing that can possibly take the place of these instruments.

Discussion

DR. F. J. PARMENTER, *Buffalo*—The control of urinary infection is paramount if the urinary tract is to be restored to its normal condition. Unless this can be accomplished,

other forms of therapy, which includes surgery, cannot be successfully carried out.

It is therefore necessary to understand the origin of the infection, the type of organ-

mentioned, germicidal substances seemed to be the logical answer to the problem of infection. I doubt if any one person could name all the germicides and antiseptics which have been injected into the urinary tract. Their very number is best evidence of their ineffectiveness.

Since the interior of the urinary tract is constantly bathed in urine, an effort to make the urine antiseptic was obvious. The two outstanding drugs for this purpose were methylene blue and hexamethylenamine. Since neither of these could be excreted in the urine in sufficient concentration to be invariably effective, numerous other drugs were tried, not only given by mouth but also injected into the veins. Some of these drugs are undoubtedly effective, but on the whole the results have been disappointing, in spite of the elaborate campaigns of commercial exploitation with which some of them have been popularized. Out of the tumult, it becomes clearer and clearer that only hexamethylenamine and perhaps acriflavine have retained any considerable part of their initial glory, and that only one really deserves a laurel crown for solid success. This is neosphenamine, which is a true specific against staphylococcus infections, often curing with a single dose and occasionally curing even in the presence of marked stasis.

Bacteriophage differs from the other members of this group, but like the others, aims to cure by direct destruction of bacteria. Few good results have been obtained with it.

Of the germicidal agents, then, we may say that in spite of enormous effort, they have been in the main a bitter disappointment. Even more than that, at the present moment we have to ask ourselves how many of the good results after injections and irrigations may have been due to the dilatation effected by the catheters used in making the injections, and how many of the good results after giving hexamethylenamine may have been due to the acidification of the urine which usually accompanies it.

The second general group of medicinal agents includes serums, vaccines, toxins, and toxoids. There has been little use for antitoxic sera, but vaccines, both autogenous and stock, have been used in

enormous quantities. Like the germicides, they have been in the main a disappointment. It is true that they have been used indiscriminately and often irrationally, and it may be that when their use is rationalized and they are not asked to do the impossible, they may become useful weapons. Of the toxins, tuberculin and various kinds of gonococcal toxins have found a few advocates, but it would be difficult at this time to evoke much enthusiasm for either. The only toxoid I can name is the staphylococcus toxoid, which has had little use, but which may also turn out to be of some value.

About twenty years ago, Dr. Raymond Hain, working in Baltimore, noted that dogs were very resistant to urinary infections, but that when they were deprived of their usual meat ration and fed on bread and milk, they became susceptible to infection. Infections so established could be cured by restoring the meat diet. Efforts to discover the cause of this phenomenon were not successful, and nothing practical came of it. A decade and a half later, interest in the subject was suddenly revived by the observation that the urine of children living on a ketogenic diet for the treatment of epilepsy was bacteriostatic, and that urinary infections disappeared from these children. The ketogenic diet was then applied to adults, and the results obtained were sufficiently good to arouse a tremendous wave of enthusiasm.

In trying to formulate the rationale of this, one runs into a curious maze of facts, clinical observations, impressions, and opinions. To begin with, the ketogenic diet consists mostly of fat, whether it be ingested fat—as in the diet of Helmholz and Clark—or the patient's own fat, as in the modification suggested by Nesbit. In deriving its energy requirements from fat, and in the absence of the usual carbohydrates, the normal body breaks down the fat incompletely, producing the ketone bodies, of which acetone and beta-oxybutyric acid are excreted in quantities in the urine. Such a urine is more acid than normal, and clinical observations shows that the acidity is so important in obtaining good results that the originators of the diet see to it that a pH of no more than 5.5 is maintained by giving, if necessary, ammonium chlor-

ide or nitrate. This throws us back at once to older observations concerning the reaction of urine in infections. Normal urine varies in reaction according to the diet, since some foods are much more acid-forming than others. It is commonly stated that colon bacilli and tubercle bacilli are found only in acid urine, yet if the pH of the urine is below five (that is, more acid than 5), colon bacilli will not grow in it. It is commonly stated that urine infected with cocci is usually alkaline, but clinical observation shows that this is not true, although there is some evidence that a urine of about pH 7.6 (7.4 being neutral) is more apt to be infected with staphylococci than with colon bacilli. Be that as it may, everyone knows that colon bacilli, staphylococci, and streptococci can flourish together in the same urine. For many years, the plan of making the urine alternately alkaline and acid has been widely used in the treatment of infections, and the indifferent results ascribed to the difficulty, by means of diet or medication, in getting it acid enough or alkaline enough. At any rate, a good many people jumped to the conclusion that the chief virtue, if not the only virtue, of the ketogenic diet was the high acidity of the urine produced, and attempted to produce the same acidity by other and simpler means. * This paper was read only a few weeks before the introductory reports of mandelic acid first came to my attention.

Discussion

DR. F. J. PARMENTER, Buffalo—The control of urinary infection is paramount if the urinary tract is to be restored to its normal condition. Unless this can be accomplished,

other forms of therapy, which includes surgery, cannot be successfully carried out.

It is therefore necessary to understand the origin of the infection, the type of organ-

ism or organisms, the degree of damage inflicted, and any mechanical factors which interfere with satisfactory drainage. To meet these requirements a thorough urological study should be made of all patients, including infants and children, in whom an infection of the urinary tract fails to clear up promptly or keeps recurring. To continue treating a case of pyuria with urinary antiseptics alone, which has failed to respond promptly, is only wasting time and the patient's money. Also, the medical attendant is discredited when the disheartened patient seeks other advice and the true cause of the pyuria is revealed and corrected. Those of us practicing urology have seen many patients who have been treated for months and years for cystitis only to learn, after much loss of time and suffering, that the origin of their infection came from an unsuspected kidney lesion, which when corrected, promptly resulted in cure.

A word about urinary antiseptics. It is obvious that the perfect urinary antiseptic is yet to be discovered, otherwise the market would not continue to be flooded with new ones and new combinations added to the old ones.

Of all these antiseptics, probably the one which has stood the test of time is hexamethylenetetramine (methenamine). Recently Schweitzer suggested combining it with camphor which he believes enhances the antiseptic value. Another chemical firm has combined methanamine with methyleneblue. And so it goes. I am sure that all the known urinary antiseptics have been tried with startling success in certain instances and as startling failures in others in which the same organism was present. This suggests that one antiseptic may act more efficaciously in one individual and a different one in another, the reason for this being unknown.

Neoarsphenamine in doses of 0.15-0.06 has acted almost specifically at times in cases of so-called sterile pyuria and in the coccus, particularly staphylococcus, infections. The dangers of the drug, however, must be borne in mind and suitable cases selected.

Urinary antiseptics should find their greatest value as a preventer of infections before and after instrumentation and operations. In infection its use should be confined to subacute and chronic infection where fluids can be safely reduced allowing the antiseptic to become concentrated. As the late Arthur Chute so often said, "Water is the best agent in acute infections." Here the antiseptic would be so diluted that its effect would be practically negligible.

Acidifying drugs. The ketogenic and

other diets are also used in the treatment of certain urinary tract infections, notably *B. coli*, and have their place in our therapeutic armamentarium.

I can heartily confirm all Dr. Davis has said, and share with him the feeling that there is still much more to be done in simplifying diets and developing methods to increase the acidity of the urine when such is needed, those in vogue having not infrequently proved disappointing.

The treatment of urinary infections may be summed up as follows:

- 1 A diagnosis (Urological examination)
- 2 Proper drainage, or removal of the affected area
- 3 Search for and removal of foci of infections when possible
- 4 The administration of urinary antiseptics, with or without additional drugs, to acidify or alkalinize the urine as the case may be, special diets, tonics, etc., as adjuncts

Finally, if the physician will think more about the diagnosis and less about therapy before such diagnosis is made, he will earn the gratitude of his patients by affording them early relief of their sufferings in the great majority of cases.

DR. GEO. W. STARK, *Syracuse*—Dr. Hunner, about 1912, read just such a paper before the New York Urological Society, and it did not go over very well. Since that time most urologists realize that urinary stasis must be overcome to successfully treat urinary infections. This point is best illustrated by pressure and urinary stasis in the pregnant woman. I have seen many a case of renal colic get well by changing the posture or by emptying the uterus, although a great many of these cases do extend into the postpartum and have to be treated by kidney lavage. These factors have been verified by means of the intravenous pyelogram.

DR. IRVING SIMONS, *New York City*—The results obtained by cystometric studies have shown us that the physiology of the bladder is a matter of great importance and has hitherto been greatly neglected.

In determining such data, I wish to state that aside from convenience of an assembled instrument for cystometry, it is necessary to have an instrument which is accurately standardized, otherwise the data is worse than none at all.

Such an instrument, the micro-cystometer and studies made with it, was presented by me at the meeting yesterday [See page 1135, August 15, 1936 issue of N. Y. S. JOUR. MED.]

DR. DAVIS (closing)—I am very grateful for the discussions which have been brought forward

I am particularly glad to hear from Dr Crance that more favorable results are being reported from nitro-hydrochloric acid

I wish to assure Dr Simons that I am not opposed to the use of cystometers. My object in referring to the use of an improvised cystometer was to stimulate interest in cystometry. As soon as anyone discovers the advantages of cystometry, he

will be anxious to procure one of the compact and convenient cystometers such as Dr Simons has constructed.

It is indeed true that Dr Hunner is the pioneer who first directed our attention to ureteral obstructions, and I am glad to do homage to him. As time goes on, I come to feel more and more that a good many of these obstructions are congenital, or at least have a congenital basis. Several of the slides I showed today depict troubles dependent on congenital malformations.

DR. FREDERICK P. REYNOLDS HONORED AT DINNER

On the occasion of Dr. Frederick P. Reynolds's retirement from the Secretaryship of the Committee on Medical Education of The New York Academy of Medicine, the members of the Committee gave a dinner in his honor, December 7, at The University Club.

The meeting was presided over by Dr. Carl Eggers, Chairman of the Committee, and was attended by the following physicians of the Committee on Medical Education: Emanuel Libman, Arthur P. Chace, Harrison S. Martland, Bernard S. Oppenheimer, F. Warner Bishop, Condit W. Cutler, Meredith F. Campbell, Ralph H. Boots, William F. MacFee, Carnes Weeks, John I. Moorhead, George Gray Ward, Charles A. Elsberg, Frederic W. Bancroft, Howard F. Shattuck, Herman O. Mosenthal, Walter P. Anderton, Lloyd F. Craver, Webb W. Weeks, Edwin G. Ramsdell, Thomas T. Mackie, Charles F. Tenney.

Present also were Major General Charles R. Reynolds, Surgeon General, U. S. Army, brother of Dr. Reynolds, and Dr. Mahlon Ashford, appointed to succeed Dr. Reynolds as Secretary.

Dr. John A. Hartwell, Director of the Academy of Medicine, who was unable to participate in the dinner, expressed his own

and the Academy's appreciations for the services rendered by Dr. Reynolds, in a letter addressed to the Committee.

"Dr. Reynolds," wrote Dr. Hartwell, "during his tenure of the directorship of the work of the Committee on Medical Education has rendered service of an outstanding character. His enthusiasm has been a constant inspiration to all the members of the committees which he has served. To my personal knowledge, no suggestion for an increased influence to the Academy in the educational field has ever failed to elicit Dr. Reynolds' enthusiastic support. His intimate knowledge of possibilities has made his guidance invaluable."

"It is not necessary to detail the actual accomplishment that has taken place under Dr. Reynolds' leadership because this is well known to the members of his Committee. However, were I able to be present, I should ask the privilege of expressing my personal gratitude and that of Dr. Williams, my predecessor, for the constant, loyal service that we have received from this very unusual man."

In addition to serving as Secretary of Medical Education, Dr. Reynolds was also Assistant Secretary of the Academy of Medicine.

AN OUTBREAK OF SMALLPOX

Health officials at Dansville, N. Y., combating an outbreak of smallpox, vaccinated 1500 adults and children in one day, early in December.

In a joint statement Dr. K. T. Rowe, village health officer, and Dr. Hollis Ingraham, State Department of Health physician, said that pupils would not be admitted to school unless vaccinated.

Their statement stressed the fact that the outbreak was mild in character.

At Hornell, where Dr. Rowe said the infection in Dansville had been traced, City Health Officer George E. Taylor reported seven cases, all previously diagnosed as chicken-pox.

Dr. Taylor ordered examination of the 3,500 school children in Hornell.

ROENTGENOLOGICAL CONSIDERATION OF DYSPHAGIA OF ESOPHAGEAL ORIGIN

JOHN M BARNES, M D, *Buffalo*

From time to time new observations in relatively well-worked fields of roentgen diagnosis call for a resummation of the available knowledge of the particular field in questions. Manges and Clerf¹ are responsible for such a recent observation in esophageal diagnosis. By means of combined roentgenologic and esophagoscopic examination, they established the group of congenitally short esophagi as another cause of dysphagia.

A review of our esophageal cases revealed a few similar cases hidden under such terms as benign partial stenosis, diverticula, and once as hiatus herniation of the cardia. The review further prompted an analysis of the roentgen methods and signs at our disposal in esophageal investigation.

Any approach to this field must be prefaced by an accounting of examination methods. We depend primarily on fluoroscopic observations following the administration of opaque materials. Of these latter, the liquid barium mixture with plenty of acacia or tragacanth is by far the most important, but the cracker crumbs and barium powder mixture of Barclay² and the opaque gelatin bougies of Hickey are also used when required. The barium filled capsule has been extremely disappointing and even misleading. It may hang incriminatingly at any of the physiologic narrowings in an entirely normal esophagus. We keep a jar of these in the laboratory principally as a reminder of past fallacies.

The patient is examined fluoroscopically in upright, supine, and at times Trendelenburg position, given sips of barium as necessary to outline the gullet. The finest focus tube compatible with load to be carried is advisable and it should hardly be necessary to stress perfect optical accommodation.

One further method of examination, of value from the standpoint of "scout" pur-

poses is the administration of a sip of barium mixture immediately before taking the routine lateral film in chest examinations. I recall one instance several years ago where this procedure would have cleared the diagnosis of a bleeding esophageal lesion in a patient who was thought clinically to have hemoptysis of phthisical origin. In this particular instance dysphagia was absent.

Stressing the roentgenological method of diagnosis should by no means detract from the importance of clinical correlation nor of esophagoscopic examination. Many of the cases encountered required full utilization of all available diagnostic measures and the fact that the roentgen method offers the best "scout" procedure should enhance rather than detract from the value of other examinations. Furthermore, it must constantly be stressed that early or small lesions may not be demonstrated at the first examination and that in the presence of persistent symptoms re-examinations must be performed until the cause is found.

The lesion found most frequently in our group is the diverticulum. Seven of these have been encountered exclusive of the Zenker's type, which actually arises in the pharynx. Fifteen outpouchings occurred opposite the hilus, two in the lower end of the esophagus immediately above the diaphragm. Their appearance is characteristic, extra luminal conical or rounded outpouchings, varying from one to four cm in diameter. The great majority were apparently primarily of the traction type resulting from contraction of paraesophageal scar tissue. Only one was responsible for clinical symptoms. In this instance the diverticulum measured approximately four cm in diameter, retained opaque material for several minutes after esophageal emptying, and produced mild substernal pressure partly relieved by coughing.

Next in frequency are esophageal neoplasms, nine being encountered. Of these, even involved the lower third, one the middle, and one the upper third. Of the ones in the lower third, over half showed obvious involvement of the cardia and only one might be regarded as relatively early.

The advanced cases showing rigidity and ragged irregular luminal narrowing and varying degrees of obstruction offer few difficulties in differential diagnosis. Benign stricture is as a rule neither so ragged nor so irregular and its longer clinical course permits a greater degree of compensatory dilatation and hypertrophy of the proximal segment. The possibility of confusion must however be admitted particularly when retained food and secretions preclude careful "relief" examination and produce suspicious filling defects.

Multiple esophageal varices might simulate the appearance of neoplasm, however the retention of pliability and distensibility of the wall in the presence of extensive filling defects should lead to a suspicion of their true nature.

The differential importance of the more unusual indurative lesions such as syphilis, tuberculosis, and actinomycosis is minimized by their remarkably low incidence and the frequent concomitant involvement of the mediastinum, pleura, lungs or skeleton. Extra luminal lesions like aneurysm, abscess, etc., not only fail to produce the rigidity seen in neoplasm but quite commonly produce displacement of the organ to a degree seen only rarely with intrinsic lesions.

The differentiation between neoplasm and cardiospasm may offer some difficulty when the cone-shaped terminus of the esophagus seen in achalasia is irregular or when a small fundal neoplasm is suspected as the exciting cause of spasm. Generally however, the esophageal dilatation, sharply localized and smooth constriction together with the fluoroscopic observation of sudden relaxation are sufficiently characteristic to identify cardiospasm. Six cases of this type have been encountered varying from very mild to quite severe.

Another group of spastic lesions of the esophagus arise as the result of the pres-

ence of foreign bodies. Opaque bodies offer no difficulty in localization or identification, however, non-opaque or minute semi-opaque bodies may defy our efforts at direct visualization. It is our practice in such cases to use thin opaque material as advocated by Moore. Frequently the foreign material has passed and only the tell-tale region of irritability or spasticity resulting from mucosal injury is found. Oddly enough two of our congenitally short esophagi have developed their symptoms within a few days of multiple tooth extractions. The narrowed area at the esophagogastric junction previously able to cope with properly masticated food was temporarily obstructed by poorly chewed food. Following regurgitation of the food particles we were able to identify the supradiaphragmatic junction of esophageal and gastric mucosa with the junctional narrowing characteristic of the condition.

A final group of spastic esophageal cases with dysphagia as their chief complaint is found in esophagitis. Four of these have been encountered, two relatively mild, two severe, one was associated with peptic ulcer at the lower end of the esophagus. In the mild cases motor hyperirritability with predominance of the circular fiber action and erratic passage of opaque material was observed. The patients complained of scratching or burning under the sternum with the quickly excited substernal ache which we have all experienced following the ingestion of very cold drinks. In both instances the previous ingestion of poorly diluted alcoholics seemed sufficient to explain the acute chemical esophagitis.

The two severe cases were somewhat less culpable both having long standing hyperacidity and pyrosis, one on the basis of gall-bladder disease, the other apparently a primary esophageal peptic ulcer. In both, motor irritability with multiple and reverse peristalsis was accompanied by intermittent spasm of the cardia. Mucosal studies revealed thickened mucosal folds showing some irregularity and multiple minute swellings. The changes in these instances were confined to the lower third of the viscus in contrast to the acute cases where diffuse involvement was found.

It is of interest that the peptic ulcer

was not picked up at the first examination but twenty-four hours later filled readily. Whether spasm, edema or retained mucus prevented filing the first time is beyond the point. The case illustrates definitely that re-examination may be necessary and offers a possible explanation

for the relatively few cases so diagnosed

HOW THE DOCTORS CAN PAY OFF THE NATIONAL DEBT

True, the doctors have expressed no wish to pay off the national debt, and many of them might remark that they had other certain small obligations that ought to have attention first. But it seems that the scheme for having them do it contemplates payments to them, not from them, so that when they have paid off the many billions of our huge national indebtedness, they will be richer than they were before.

Of course we are living in an age of financial legerdemain and economic kaleidoscopy, but this seeming fantasy is presented in the usually sober *Public Health Reports*, issued by the U. S. Treasury Department, and is from the pen of Dean K. Brundage, Senior Statistician of the Office of Industrial Hygiene and Sanitation of the U. S. Public Health Service. Not to keep it a secret any longer, his idea is that if employers would provide adequate medical care for their workers, the annual saving to industry would soon be enough to liquidate our national obligations. Incidentally, the demand for additional medical attention would keep all the doctors busy and solve their own economic dilemmas.

Our statistical expert, after preliminary figuring too extended to quote here, calculates that a reasonable reduction in sickness and accident rates in an average plant would result in savings of "at least \$12,600 per annum per 1,000 employees. It appears, therefore, that an employer can afford to spend at least \$12,000 per year per 1,000 employees for preventing accidents and conserving health when his industrial accident rate is considerably below the average for industries covered by workmen's compensation law, and when there are a negligible number of illnesses among his workmen attributable to occupational health hazards. When industrial accidents or disabling illnesses occur at average or above average frequency, an expenditure larger than that indicated above for health and safety work obviously is warranted."

The higher sum may be warranted if

there is a hazard in the industry, we are told.

The expenditure of \$12,000 annually per 1,000 employees, estimated as warranted from an economic standpoint, may be appreciably increased when even a small percentage of the workers handle materials or are engaged in processes which may affect health adversely. The size of the extra appropriation needed for protection of the exposed workers obviously depends on the severity of the hazard. The direct and hidden costs of a single minor hazard might easily total \$8,000 per year, in which event an expenditure of \$20,000 per annum per 1,000 employees would be warranted for adequate health and accident protection. Or, in the absence of any industrial health hazard, an appropriation of an additional \$6,000 per year per 1,000 workers could be justified on the basis of its value to employees, for effective industrial medical service saves the workers at least \$6.20 per capita per year.

Now we come to the national debt, which our statistical expert brings into the picture in this impressive fashion:

The consumer seldom realizes the extent to which the costs of industrial accidents and sickness add to the price of products, or, stated another way, decrease the purchasing power of the dollar. The expenditure for medical care in the United States appears to have been approximately \$3,600,000,000 in 1929. If the indirect or hidden costs of sickness and accident are assumed to be only 28 times the direct costs instead of 40 times as was found for industrial accidents, the annual bill to the Nation is about \$10,000,000,000. An item of this magnitude obviously is an important factor in the cost of living.

One has to resort to the national debt to obtain figures large enough for comparative purposes. A 10 per cent reduction in accident and sickness, if maintained, would constitute a saving equivalent to liquidation, in slightly less than 3½ decades, of the present national debt of approximately \$34,000,000,000, a 20 per cent decrease would save enough to pay the entire sum in 17 years. A decrease of 10 to 20 per cent in the incidence of accidents and in the time lost from sickness with accompanying prolongation of the average duration of life is not a visionary, impractical goal, judging from experience along that portion of the road in this direction which we have already traversed.

COARCTATION OF THE AORTA

With Report of a Living Case

SAMUEL GITLOW, M.D., *Bronx*

Associate Physician and Pathologist, Lebanon Hospital

Coarctation of the aorta is a constriction or atresia of the aorta in the region of its juncture with the ductus arteriosus or its vestige

Bonnet¹ divided the condition into the infantile and the adult type. In the infantile type there is a narrowing of the aorta between the origin of the left subclavian artery and the insertion of the ductus arteriosus. This is the region of the fetal aortic isthmus and therefore represents an exaggeration or persistence of the anatomical conditions existing before birth.² In the adult type the constriction is at or just distal to the ligamentum arteriosum. It has no counterpart in fetal life and it is for this reason that Bonnet established this classification considering the cause of the condition as something occurring in postnatal life.

However, Evans³ of the Cardiac Clinic of the London Hospital departed from this classification and divided coarctation into six types in a most satisfactory manner thus:

Type I Congenital stenosis of the aortic arch with a patent ductus arteriosus and hypoplasia of the proximal portion of the aorta. There are no large collaterals.

Type II Congenital stenosis of the aortic arch with a closed ductus arteriosus and hypertrophy of the proximal portion of the aorta. This type has a very pronounced collateral circulation and has the longest expectancy of life.

Type III Congenital atresia of the distal portion of the aortic arch with a closed ductus arteriosus and hypertrophy of the proximal portion of the aorta. This type is quite rare, the collaterals are large but it is compatible with life.

Type IV Interruption of the aortic arch in its distal portion with the ductus arteriosus widely open and hypoplasia of the proximal portion of the aorta. The collateral circulation is very large. The condition is rare.

Type V Congenital atresia of the proximal portion of the aortic arch with a patent ductus arteriosus. These cases live days only.

Type VI Congenital absence of the ascending aorta with a widely patent ductus arteriosus. These are examples of the rare corbiloculare.

Only types II and III are of clinical importance inasmuch as they are compatible with more or less prolonged life and may therefore be diagnosed during life.

The condition was first discovered by Morgagni⁴ in 1760. The first case was described by Paris⁵ in 1791. The infantile type was diagnosed only once in a child of three. In 1835 Legrand⁶ and Mercier⁷ in 1839 made a diagnosis of obstruction of the thoracic aorta. Oppolzer⁸ made the first diagnosis of coarctation of the aorta at the site of election. His two diagnosed cases were confirmed by autopsy and he gave a very accurate description of the diagnostic criteria.

The constriction of the aorta is of varying degrees but always occurs at or just distal to the insertion of the ductus arteriosus or the ligamentum arteriosum.

Externally there is a sharp inward kinking and annular thickening of the aortic wall which appears as if a ligature were tied about the vessel. Within, the lumen of the aorta may be further encroached upon or even occluded by a septum or diaphragm with or without an aperture in the center which is usually triangular. This septum or diaphragm is made up of the inner coats of the aorta.

The ductus arteriosus may be converted into a fibrous cord or one of its ends may be open and become dilated even to the extent of aneurysm formation and the possibility of rupture and death.

In the majority of cases there is dilatation of the ascending aorta as also left heart hypertrophy. This does not occur if the ductus arteriosus is widely patent for then there is right heart hypertrophy and hypoplasia of the ascending aorta.

The major part of the collateral circulation takes place between the superior intercostal branch of the subclavian artery

and the first aortic intercostal which springs from the aorta just below the constriction. This connection takes place by way of the posterior scapular, the interscapular, and the subscapular arteries which pierce the intercostal spaces from behind and pour the blood coming to them from the ascending aorta by way of the subclavians into the second and sometimes the fourth aortic intercostal arteries which conduct the blood together with that from the internal mammary arteries into the descending thoracic aorta below the constriction. The volume of blood so received is often so great that it causes a dilatation which may be aneurysmal or it may produce atheroma which may in time be the site of rupture right through or between the aortic coats (dissecting aneurysm). The aorta resumes normal size at the level of the fourth or fifth intercostal arteries.

The whole collateral circulation may be hidden in the posterior part of the chest and so not be visible.

The collateral circulation may take the path of the internal mammary arteries, connect with the epigastric branches of the external iliac arteries over the abdominal wall where they present themselves as large, whipcord tortuous trunks or as cirroid aneurysmal like bunches which may also be found in the axilla.

In both instances the collateral circulation arises from the subclavian arteries and both types may be present in the same patient.

There are frequently associated aneurysmal dilatations of the arteries of the brain particularly in the region of the circle of Willis and these may be the source of frank or intermittent cerebral hemorrhage.

These cases—particularly the infantile type—have frequently associated anomalies of the cardiovascular system as also of other viscera of the body.

There are two theories of the origin of coarctation of the aorta. (1) The Paulo-postnatal or Skodaic theory and (2) the faulty development theory.

The first according to Abbott² was indicated by Craigie⁹ in 1841 when he considered the obliterating process in the ductus arteriosus to extend into the aorta and so cause narrowing. This theory was later elaborated by Skoda¹⁰ and is

the one that Bonnet¹ accepts. Against this, however, is the fact that ductal tissue has never been found in the aorta.

Faulty development as a cause was first suggested by Raynaud in 1828. This is the theory accepted by most recent workers as also by Maude Abbott² and by Blackford.¹¹ Since the distal portion of the fourth aortic arch of the aortic arch system forms the part of the aorta at and near the ductus arteriosus, it is thought that some maldevelopment of this arch is the cause of the condition. It may be that some traction at this point may be the cause.²

The symptomatology is vague. Patients may continue into adult life before showing any symptoms. It is then latent until the patient may show a sudden break in cardiac compensation or suddenly have a cerebral or intrathoracic hemorrhage, the latter usually from a ruptured aorta or aneurysm or dissecting aneurysm. More commonly they exhibit a history of mild cardiovascular symptoms such as breathlessness on exertion, coldness of the lower extremities, headache, cramps in the legs, etc. These patients may have much better development of the upper part of the body than of the lower, they are above the average in intelligence, are athletic, and may exhibit the symptoms of hyperthyroidism.

On examination there is noticed a marked throbbing pulsation of the vessels of the neck which may also be felt to be much enlarged. Such pulsation and such vessels are also seen—but not in all cases—in the vessels about the scapula and in the intercostal spaces, as also over the abdomen. Sometimes grape-like bunches of dilated vessels may be observed over the abdomen or in the axilla looking like cirroid aneurysms.

On palpation the forcible pulsations and the hypertrophied vessels are felt in all these locations. The abdominal aortic pulsation is diminished as well as that of the femoral, the popliteal, the dorsalis pedis, and the posterior tibial arteries.

On auscultation there is usually heard a loud rough systolic murmur over the entire heart, more marked over the parasternal regions and over the aortic area. This murmur is often halo—or postsystolic² in time occurring just after the first heart sound. The murmur, while

it may be produced by the hypertrophy that accompanies the existing hypertension is usually produced by the current of blood in the enlarged and thickened internal mammary arteries. A similar rough systolic and sometimes diastolic murmur is heard over the enlarged and thickened collateral vessels in the interscapular space particularly the left.

The heart is enlarged to the left and the aortic dulness is widened.

The blood pressure in the arm exhibits hypertension while that in the lower extremities is either normal or low. Normally the blood pressure in the lower extremities is twenty mm or more above the upper.

On roentgenography the following direct evidences are found according to Fray¹²

- 1 No aortic knob—not pathognomonic
- 2 Defect or break in the continuity of the aortic arch in its descending limb in the left oblique film. This is pathognomonic. There may also be seen an indentation of the arch usually on its convexity.

Also the following indirect evidences

- 1 Left ventricular hypertrophy (blunt apex)
- 2 Dilatation proximal part of aorta
- 3 Erosions of the ribs. Is pathognomonic. These rib erosions are very important. Fray lists their characteristics as follows:
 - a. Multiple. May be more than one on one rib.
 - b. Involves only the lower rib margins.
 - c. Bilateral usually involving the posterior portions of the ribs as far as the posterior axillary lines.
 - d. Sulcation is smoothly curvilinear never rough or angulated.
 - e. No other alterations of the ribs.
 - f. None or little evidence of new bone formation. Upper line may show increased density.
 - g. No pathological fracture.

These rib erosions were first noted by Meckel¹⁷ in his classic illustration and reported by Craigie⁹ in 1841. First clinically reported by Rösler¹³.

The lower extremities may show a lower temperature than the upper even to the touch (Schapiro)¹⁴.

Blumgart, Lawrence, and Ernestene¹⁵ studied the dynamics of the circulation in two living patients.

There is a retardation and diminution of the femoral pulse. The femoral pulse ordinarily precedes the radial by 0.01–0.02 second. In these patients it was the re-

verse by 0.15 and 0.05 second respectively. The reason for the normal difference is that the heart to radial distance is greater than the heart to femoral. Dock and Raisbeck¹⁰ got the same reversal but the delay was only 0.02 second. In coarctation, the delay is due to the greater time required for passing the collaterals than for the normally direct route through the aorta thus making heart to femoral distance greater than heart to radial.

The diminution of pulse as pointed out by Bonnet¹ and restated by Maude Abbott² and Blackford¹¹ is due to the fact that the passage through the collaterals flattens out the pulse resulting in a slow rise and fall instead of the rapid that is normal. This slow rise and fall transmits the impression of smallness to the finger.

In one patient, tested, the femoral oxygen saturation was less than that of the brachial, perhaps because of the utilization of oxygen in passing through the large network of capillaries of the collateral circulation.

The velocity of the circulation, heart to femoral artery, was eleven seconds and femoral vein to heart nine seconds which is a reversal of the normal, again indicating the circuitous route used.

The diagnosis of coarctation rests upon the blood pressure difference between the upper and lower extremities, the demonstration of a collateral hypertrophied circulation, a diminished abdominal aortic pulse, a delayed and diminished femoral pulse, and the x-ray evidences in the aorta and heart, and particularly of the collateral circulation in the form of visible vessels, pulsations, and rib erosions. The most important single sign is the blood pressure difference.

These cases are usually seriously stricken in the prime of life if they survive the first few postnatal days. The modes of death are usually

- 1 Rupture aorta (aneurysmal or direct)
- 2 Cerebral hemorrhage
- 3 Subacute or acute bacterial endarteritis
- 4 Cardiac failure.

Case Report

A V, aged 26, first came under my observation eight years ago (1926) because he had been rejected for a bank position be-

cause of hypertension. His previous history was entirely negative except for pneumonia five or six years previously. For the past three years he had some shortness of breath, but only after running. He was athletic.

On examination at that time he had throbbing vessels in the neck, a heart somewhat enlarged to the left, and a systolic murmur heard all over the precordium and of maximum intensity over the aortic area. This murmur was also heard in the back. His brachial blood pressure was 160/88. He seemed in good condition, was given no medication, but cautioned about activity.

I next saw him six years later and this time suspected the diagnosis. He worked for a leading explosive powder company whose medical department examined him thoroughly. X-ray was reported as showing mitral configuration of the heart with slight left ventricular hypertrophy. EKG negative. His blood pressure at this time

was 152/90, abdominal aortic pulsation was weak as also his femoral. The dorsalis pedis and posterior tibial pulsations were not felt. Blood pressure of his lower extremities was not done at this time but eight months later his brachial blood pressure was 190/100 and the femoral systolic by palpation was 132.

His former x-rays were now secured and showed the absence of an aortic knob (particularly in the presence of hypertension), a heart enlarged slightly to the left, a failure to visualize the descending aorta in the left oblique film, and erosions of the ribs. The patient was again very kindly roentgenographed for me by Dr. Sydney Wentraub of the New York Hospital and again showed the same findings.

The patient is intelligent, athletic in build and temper, and has somewhat better developed upper half of body than lower.

865 WALTON AVE.

HOW NOT TO CROSS THE STREET

Londoners have had a lot of entertainment recently from a police car with a loud speaker stationed at busy crossings and warning people walking dangerously.

A powerful voice—though not always powerful enough to dominate the noisy traffic—would suddenly call out to an offender:

"Don't cross among the stationary traffic like that. It is very dangerous. You were nearly run over then, you know."

Sometimes the voice particularized its victim—

"The lady in the black coat—that's not the way to cross the street, madam. It's particularly unsafe, in fact. Always use the recognized crossing."

That was the general tenor of the official advice—to wait for the traffic to stop and, in the meaning—"don't dodge about, please."

The exhortations conveyed a lesson not only to those addressed, but to all within hearing. Especially in the morning, more and more of the passers-by who had time to kill became stationary and interested spectators. In the embarrassment of the men and women addressed individually they had discovered a grand free entertainment—a new and rich addition to those which the streets of London can always offer.

But even those who stayed to smile may have received some more substantial benefit than mere amusement. The more diffident among the people who were singled out, however politely, may decide in future to choose another crossing-place—one with no cautionary voice and no publicity for sinners.

VARICOSE VEINS AND VARICOSE ULCERS

Technic of the Injection Treatment

HAROLD J. SHELLEY, M.D., *New York City*

Assistant Attending Surgeon and Chief of Surgical Clinic St. Luke's Hospital

In this paper I shall not give the details as to what the injection of varicose veins and varicose ulcers will accomplish. In the past several years, this has been written about and demonstrated by pictures so thoroughly, that I shall pass as an accepted fact that the proper injection treatment of varicose veins will safely eradicate those veins and cure varicose ulcers. It must be understood that not all leg ulcers are varicose ulcers, and the injection of veins cannot be expected to heal other than actual varicose ulcers. What I shall present is an outline of the present method of treatment of varicose veins and varicose ulcers which I use in my office and in the clinic at St. Luke's Hospital.

Treatment

Preparation of the patient. A thorough physical examination with urinalysis and blood Wassermann, should precede the injection treatment. Any abnormal condition, such as diabetes, high blood pressure and lues, should first be treated. Foci of infection, particularly in the teeth, tonsils, and sinuses, should be cleaned up.

The condition of the deep circulation is determined. Present or past phlebitis or thrombophlebitis must be looked for in the history and physical examination.

The following points are to be borne in mind if the treatment is to proceed rapidly and smoothly. Proper shoes are fitted and flat feet corrected. No constricting clothing is permitted about the legs. Any calcium deficiency should be corrected. Thyroid hyperfunction or deficiency is to be cared for. As much excess weight as possible should be removed.

If the patient's occupation necessitates his standing for long periods, he is required to walk about at intervals during his working hours. All other patients are instructed to continue their customary amount of walking, or if very little is

done, to increase it moderately. A patient confined to bed should not have injections.

Varicose veins. The skin is prepared with seventy to seventy-five per cent alcohol. The injection is ordinarily made with the patient sitting, although in some cases the veins will fill better when the patient stands. Rarely a tourniquet is used to distend the vein or to maintain for a time the contact of the solution with the vein wall. The veins are injected first in the feet and then progressively up the leg, entirely to the saphenous opening if they can be seen or palpated that high.

The use of very sharp needles without too long a bevel is most important in doing the injections with ease and without complications. For the larger veins, a one inch 21 or 22 ga. needle is used and for the very small veins a 24 or 26 ga. needle is satisfactory.

A small initial dose of the drug used (either quinine and urethane or sodium morrhuate) is given to determine the possibility of idiosyncrasy and the extent of closure of each individual patient's veins. A few seconds after the injection or the injections are made, the foot is elevated so that it is slightly higher than the hip. This is done because in some veins there is no appreciable circulation and as a result the medication damages the vein wall too severely. Also the drug may remain in the thrombus with resulting pain and inflammation or it may indeed actually prevent thrombosis.

Two to five days later, the patient should be seen again. From the extent of the thrombosis which has occurred the subsequent dosage can be approximated for the various sized veins. At each visit a sufficient number of veins are injected to use five c.c. of the sodium morrhuate, or two c.c. of the quinine hydrochloride and urethane solution.

From the Out-Patient Department of St. Luke's Hospital

If much swelling ensues, an Ace bandage is kept on the leg at all times the patient is out of bed. A certain amount of aching or soreness will result which is readily controlled by aspirin and the application of heat, unless the dosage has been too large, or the drug allowed to remain in the vein too long.

All visible and palpable veins are injected. If the saphenous can not be injected in its full length, it is cut and ligated immediately distal to its entrance into the femoral vein. There should be no veins left entering between the site of ligation and the junction with the femoral. If the patient is so obese that it has been impossible to inject the veins above the knee, an injection is made into the vein distal to the ligation before the incision is closed. This whole procedure can be done easily in the office under novocain anesthesia and the patient permitted to walk out of the office, even if both sides are done at one time.

In the dilated capillaries and small veins, only sodium morrhuate is used, as the quinine solution may pass through the wall in sufficient quantities to cause a superficial skin necrosis. For the same reason only a limited number of these small veins should be injected in any area at one time.

If, due to faulty insertion of the needle or movement on the patient's part, some of the solution is placed outside the vein wall, ten c.c. or more of normal saline, or an equal amount of blood from another vein, is immediately infiltrated through and around this area. If an extravasation occurs it can usually be noted at once as the patient complains of a stinging sensation or more than normal pressure is required to force the solution through the needle.

Varicose ulcers. Many writers advocate cleaning up the ulcer before starting the injections. I begin the injections at once, but use first only small amounts of the solution and increase them slowly, watching carefully for evidence of infection in the thrombi. The eradication of the veins is the most important part of the treatment of the ulcer and the first injected are those nearest to it.

At each visit the ulcer is scrubbed carefully with benzene. When this is thoroughly evaporated, a Lassar's paste

dressing is applied with pressure from either a firm gauze or Ace bandage. If healing appears to proceed too slowly, a rubber bath sponge split in half, is incorporated in the dressing over the ulcer, or an elastoplast bandage may be applied at each visit.

When all visible or palpable veins are injected and the saphenous ligated if necessary, the ulcer will usually be healed. If it is not, an elastoplast bandage or Unna's paste boot is applied, including the foot, ankle, and leg to the knee. This is removed every two to four weeks, and before reapplication all veins which can be found are injected.

This will practically always result in healing. In a few cases skin grafting will be found necessary.

Aftercare. When the veins are apparently all closed, the patient is requested to report at intervals of three months for two years, and, if possible, once a year after that. Any veins disclosed by careful inspection and palpation are injected.

Prevention and Treatment of Complications

Pulmonary embolus. This is a very rare occurrence with the injection treatment. It should not occur if the patient follows instructions as to exercise and there is no active phlebitis present at the time of injection. The treatment is the same as that of pulmonary embolus from any other cause.

Sclerosing phlebitis. If not transitory, this usually occurs when, due to poor venous circulation, some of the sclerosing solution remains in the vein long enough to be included in the thrombus. Thrombosis may even be prevented. A painful indurated red area appears along the involved vein. The treatment is chiefly prophylactic. If after the injection the leg is elevated, all of the solution will be carried into the general circulation and this condition cannot occur.

Should it occur, however, a small incision into the involved vein is made with novocain anesthesia, under carefully maintained asepsis. The contents of the vein are gently expressed and a sterile dressing applied with pressure along the involved vein. Prompt relief from pain is obtained and healing of the incision and the vein occurs by primary intention.

Slough If an appreciable amount of the sclerosing solution is deposited outside of the vein and not diluted by the infiltration of saline solution or the patient's blood, an area of necrosis will result. Should this happen, the area is excised, the resulting cavity packed with iodoform gauze, and a boric ointment dressing applied. At intervals of every two to three days, the wound is cleansed with benzene and dressed as at the time of excision. The area will clean up slowly, granulate in and leave only a relatively small but, usually somewhat pigmented scar.

Sloughs from the injection of small superficial veins can be prevented by the care in not injecting too many veins in closely adjacent areas of skin, using very little pressure in the injection, and always making certain that the entire bevel of the needle is within the lumen of the vein.

Sensitivity to sclerosing drug Careful questioning as to previous evidence of sensitivity to quinine, if that is the drug to be used, will avoid a frequent occurrence of this complication. Should the patient have an anaphylactic reaction after the injection, the immediate use of fifteen minims of 1:1000 solution of adrenalin hydrochloride subcutaneously will give complete relief excepting in a few cases in which the use of more of the same solution will be found necessary. Naturally a drug other than the one to which the patient is sensitive is used for the completion of the treatment.

Infection of the thrombi This ordinarily occurs because of the undiscovered presence of a pre-existing thrombophlebitis, and the treatment is that of the thrombophlebitis. It may also be due to the presence of undiscovered foci of infection, particularly infected teeth. Treatment should be interrupted long enough to clear up all foci of infection. The local condition is treated as any other phlebitis.

Failures

Recanalization This does happen, but

in my experience, very rarely. Possibly it is due to using too weak or too small amounts of sclerosing solution. Failure to inject the deeper varicose veins and to close the saphenous, probably have a considerable influence in producing this sequela. The treatment is reinjection and closure also of all varicose veins above the area involved.

New varices A patient who has developed varicose veins can develop more after those first present are eradicated. This is the reason that all patients are requested to return for examination at intervals after the apparent completion of the treatment. All varices are injected as they appear.

Residual symptoms of varicose veins These are invariably due to the fact that not all of the varicose veins have been closed although there are apparently no more present. Those deep in the subcutaneous tissues cannot be seen. Careful palpation will reveal their location excepting in the most obese patients. As mentioned before, ligation and distal injection of the saphenous will care for these cases.

Difficult closure This is one of the most common causes of failure in the treatment, probably second only to failure to find all of the involved veins. An increase in the amount or strength of the solution used will usually result in closure. If not, the solution is kept in the vein for a longer time by having the patient stand or by using a tourniquet. The time required can be determined only by increasing the period of time with each injection until a satisfactory closure is obtained. Removing the blood from the vein between tourniquets and then injecting the empty vein will give the same result.

Mistaken diagnosis If the symptoms present, or the ulcer on the leg are due to causes other than varicose veins, naturally treatment of the varicose veins cannot be expected to result in a cure.

182 E. 79 St

The Medical Society of the County of New York has formed a lecture bureau to provide speakers for lay organizations and is now developing a list of physicians who

are willing to give addresses. Members of the committee in charge of the bureau are Drs. Clarence G. Bandler, Peter Irving, and Alfred M. Hellman.

TWELVE YEAR MEDICAL SURVEY OF A LARGE COMMERCIAL ORGANIZATION

R FRANKLIN CARTER, M D, F HOWARD WESTCOTT, M D, and
A W ALLEN, M D, *New York City*

The Medical Department* is made up of a director who is also the surgeon, an internist who comes in daily, an eye, ear, nose, and throat specialist who holds clinic bi-weekly and a dentist who holds clinic on consultation day. These are assisted by a registered nurse and an experienced physiotherapist. A second registered nurse does the visiting and acts as relief clinic assistant. Adequate clerical assistants complete the personnel.

The work in our department consists in the examination of new employees, care of insurance cases, and minor medical needs as they arise on the premises. A general consultation clinic is held each week. A record of physical examinations, subsequent visits, and all absences due to sickness or injury is kept for each patient. The data to be presented was obtained from a study of these charts.

Our physical examination is similar to that required by large insurance companies. There are two classes made with respect to employment—those that pass and those that do not. For purposes of purely medical interest, all individuals are divided into four groups: A, B, C, and D. The first three are acceptable, the last, not acceptable. All the medical information and records are the property of the Medical Department and no rating other than "passed" or "D" (failed to pass) appears on any personal card outside of the department.

The medical groups are

A. Physically fit. No defects.

B. Physically fit. Defects of a minor nature, such as bad teeth, tonsils, etc., that could be easily eliminated to leave the individual in Class A standing. A follow-up has been conducted on these individuals.

C. Physically fit. Defects of a fixed nature, that in no way interfere with the expected longevity and usefulness of the

employee, such as loss of a limb, one eye, healed fractures, etc.

D. Physically unfit. Defects that either decrease the normal life expectancy or interfere with the duties of the employee. Any history or sign of tuberculosis, ulcer, gall bladder disturbance, heart, kidney or mental diseases.

In making a medical survey of a large commercial organization, we have found that the material could be presented in one of several forms, depending upon what points of interest we wished to emphasize.

Our first presentation by Dr. R. Franklin Carter¹ portrayed the general scheme of the Medical Department. When he organized the department in 1921, there were approximately 1963 employees who had been selected naturally, with no medical examination. These have been called the "No Examination" group and have served as our controls for comparison with those subsequently employed. All employees hired from 1922 have been examined and classified according to the qualifications noted above. He showed in very detailed charts, the value to the employer of such a medical selection. A second valuable conclusion showed very clearly that, by our present-day methods of examining and classifying the applicants, we could group them in such a way that valuable comparative studies could be made. These studies of the various groups have afforded us positive means of checking up the efficiency of our Medical Department.

One of the startling facts uncovered by our study was the exceedingly high percentage of time lost because of illness as compared to the time lost from accidents. This imbalance has become more marked as working conditions have improved and as the need to hurry decreased with the changed economic conditions. Thus, for 1921-31, 1931, and 1932, the figures in Table I demonstrate the change.

* Medical Dept. of the New York Times

TABLE I

No. of Employees	Days lost	No of days lost		Percentage of time lost	
		<i>Illness</i>	<i>Injury</i>	<i>Illness</i>	<i>Injury</i>
(1921-31) 2548	69 959	49,462	20 497	70 7	29 3
(1931) 2932	17 134	13 250	3884	77 3	22 7
(1932) 2992	14 512	11,441	3071	78 8	21 2

The relative percentage of time lost from illness is approximately the same in all groups, but the total time lost increased in each group from "A" to "D" and the "No Examination Group." For example, in the non-selected group, the percentage of time lost for illness was 71.2, seventy-eight, and eighty-one per cent, and in the unacceptable group, 83.3, eighty-six, and eighty-two per cent respectively. It would seem that the chief value of classifying employees was in respect to potential illness and not to forecast possible injury absences.

Table II illustrates the Cost per Man per Year for illness over a ten-year period and two subsequent one-year periods. They are based on an average salary of \$7.00 per day.

In a further analysis of these figures, it is important to segregate those types of illnesses which make up the majority of these absences. In order to make the analysis concise and easily understandable, we have grouped the diseases according to systems and the following outline will be followed

1 *Respiratory Diseases* Common colds, influenza, grippe, bronchitis, pneumonia, pleurisy, tuberculosis, and asthma comprise this group

2 *Miscellaneous diseases* Metabolic diseases, skin, nephritis, asthenia, and nervous and mental disturbances are included in this group

3 *Miscellaneous infections* These include arthritis, rheumatism, lues, adenitis, boils, infections of extremities, etc

4 *Gastrointestinal diseases* Liver, gall-bladder, and rectum are included.

5 *Ear, nose, and throat diseases* Illnesses pertaining to the upper respiratory tract are considered in this group

TABLE II

Group	1921-31	1931	1937	Average
A	\$17 50	\$18 68	\$17 17	\$17 78

Grand total	10 095	74,153	13.6

6 Cardiovascular diseases Hypertension and arteriosclerosis are included in this group

7 Genitourinary diseases Gynecological conditions are also contained in this group

The analysis in Table IV would indicate that respiratory disease accounts for approximately 34.3 per cent of the time lost because of illness and thus becomes a very important item and a likely spot to attack in bringing down the cost of health insurance

In interpreting these tables, one must remember that it is sometimes difficult to exactly differentiate between colds, grippe, influenza, and mixed acute respiratory infections. Another source of error is among the cases which come in after having been absent and give their own diagnosis or bring in a medical certificate with one rather vague diagnosis or with several from which to choose. Our figures were compiled with these thoughts in mind and we believe they will compare favorably with future more carefully controlled special studies

Several groups of diseases were combined in Table V in order to make the presentation more compact and valuable. Detailed tables, such as shown for the respiratory diseases, are being eliminated in order to conserve space and only the summary tables are presented

It is not surprising that the highest figures are found in the older group of unexamined employees, because all cases of diabetes, nephritis, hyperthyroidism, etc., were rejected in hiring new employees. In spite of this nonselective hiring, a surprisingly low percentage of workers lose time for these illnesses which play such an important part in one's medical practice and clinic work. The most important causes for absence in this miscellaneous group were nervous upsets and definite mental states of various types. Although we have the usual numbers of diabetes and chronic nephritis, they rarely are ill enough to stay at home.

By far the most important infectious conditions, which were not associated with accidental causes, were the arthritic or rheumatic infections. These high figures are the result of prolonged absences by a few employees in contrast to the respiratory disease absences which were usually

of short duration but in endemic proportions. Although numerous cases of syphilis were encountered, these people, unless acutely ill, preferred to work and in many instances did not report to the Medical Department until after the acute stage was over (Table VI)

The absences classified under group in Table VII of diseases are made up primarily of numerous short illnesses called "acute indigestion," "stomach trouble," "food poisoning," etc. The most frequent organic diseases were the ulcers and gall-bladders. Absences from "operative appendicitis" was the largest single cause for lost time in the entire group and vividly brought to our attention the frequency which this condition is diagnosed.

A more detailed analysis of this important field and its relation to industrial medicine and health insurance is being made and will be reported at a later date. Table VIII is included here only to show its relative position in comparison with the whole.

The cardiovascular diseases as a cause of absence can be practically eliminated by careful selective choice of employees, at least during the first ten or twelve years of their employment. After this first period has passed, the increased age incidence will undoubtedly bring the figures up nearer to those found in our control group of unexamined employees. It should never equal the latter figures because, as we can see in the table of rejections, there are forty definite cardinals who would otherwise have been accepted

and increased the days of absence much sooner than the expected free period of ten years.

The most frequent cause for absence among cardinals is the onset of decompensation. The second most common causes are coronary disease and hypertension, which made up the bulk of the remaining absences.

TABLE VIII—SUMMARY OF TIME LOST DUE TO EAR, NOSE, AND THROAT CONDITIONS FOR 12-YR. PERIOD

Group	Days lost due to ear, nose and throat conditions	Total number of days lost	% of time lost for illness due to ear, nose and throat conditions
A	1 233	7 216	17 0
B	2 504	16 454	15 1
C	822	7 410	11 0
Sub-total	4 559	31 080	14 6
No Px	2 664	40 291	6 6
D	31	2 782	1 1

Grand total	5 018	74 153	6 7

CHART I—DISTRIBUTION OF TIME LOST IN 12 YR. PERIOD

TABLE X—SUMMARY OF TIME LOST DUE TO GENITOURINARY DISEASES FOR A 12-YR. PERIOD

Group	Days last due to genito-urinary diseases	Total number of days last	% of time lost for illness due to genito-urinary diseases
A	168	7,216	2.3
B	1,048	16,454	6.3
C	448	7,410	6.0
Sub-total	1,664	31,080	5.3
No Px	1,369	40,291	3.4
D	0	2,782	0
Grand total	3,033	74,153	4.0

The surprising finding in Table X is the relative unimportance of dysmenorrhea as a cause for absence. Venereal disease, excluding syphilis, is the one of greatest importance in this field. The bulk of the remaining absences was composed of isolated single cases, many of which were surgical.

The accompanying Chart I illustrates the relative importance of these groups graphically. The perpendicular lines represent days of absence covering a period of twelve consecutive years.

Rejections

The original causes for rejection are still in force, but in addition we have included some which we have learned from experience were of importance. Our original standards for allergic individuals have been somewhat more elastic in recent months and all except frank asthmatics are now accepted, if otherwise normal conditions exist. Table XI gives the figures for rejections for the twelve-year period under consideration.

Summary

In summarizing this work, we feel that the three following statements can be amply justified:

1. Rejection of applicants with pre-employment diseased conditions was justified and the cost to the organization of

TABLE XI—NUMBER OF REJECTIONS AS COMPARED WITH PHYSICAL EXAMINATIONS

Year	Physical examinations	Rejections
1930	756	48 (6.3%)
1931	605	41 (6.7%)
1932	204	15 (7.3%)

CAUSES OF REJECTIONS		1930	1931	1932
Diagnosis				
1 Hypertension		8	9	8
2 Kidney conditions		7	12	1
3 Cardiac conditions		12	3	0
4 Suspicious chest		1	2	2
5 Eye conditions		3	0	1
6 Age		0	3	2
7 Diabetes		0	2	0
8 History of venereal disease		1	0	0
9 History of typhoid		0	1	0
10 History and general condition		0	1	0
11 Mental deficiency		0	1	0
12 Defective hearing		0	1	0
13 Possible CA of sigmoid		1	0	0
14 Suspicious genitourinary history		0	0	1
15 Failure to complete examination		15	6	0
Totals		48	41	15

similar control cases hired before examinations were required was determined.

2. Grouping of the accepted applicants according to the above mentioned scheme proved that, by such separation, we empirically divided them according to the relative cost of sick absences. A prediction of the amount of time lost in each group can thus be made.

3. By such selective hiring, a plan can be formulated whereby all applicants can be hired, provided a graded sick benefit plan is adopted. This eliminates the danger of setting up a social inequality as exists now by rejecting certain applicants.

Future surveys may add more valuable information, but we believe that only through such experience will the medical profession be able to continue to give medical care and also direct themselves in the field of industrial medicine of the near future.

N Y U ALUMNI ELECT

The New York University College of Medicine Alumni Association announces the election of the following officers: President, Robert P. Wadhams, '06, Vice-President, E.

David Friedman, '07, Secretary, James W. Smith, '17, Treasurer, H. Harold Lardaro, '24. The next Alumni Day will be held at the College on February 20.

MONGOLISM OCCURRING IN AMERICAN INDIANS

Report of Three Cases

JACOB SIRKIN, M D, *Newark*

From the Newark State School

In a recent article, Gesell¹ made a survey of the literature pertaining to mongolism occurring in the colored races. He found reports of cases occurring in Negroes, Chinese, Japanese, a Hindu, and a West Indian, but was unable to find any instance of mongolism occurring in American Indians.²

Therefore, since the literature contains no mention of American Indian mongolism, it was felt worthwhile to report the following three cases observed at the Newark State School.

CASE 1 P.L., female, age nine, American Indian, I Q 20 (Fig 1). Her father was a Cattaraugus Indian and mother, an Allegany Indian. Family history is negative, with no mental or nervous disease having been present. Mother was forty-seven years of age at time of patient's birth. Patient was third in order of four children in family, the other children being fourteen, twelve, and eight years old, respectively. All

are girls. There were no prenatal irregularities other than vomiting almost after every meal for the first three months of gestation. Delivery was spontaneous, pregnancy was full term. She was breast-fed and weaned at approximately one year of age. She was unusually fat for a child of her age, did not walk until the age of three and has never talked.

Physical examination. Patient is a somewhat stocky, overweight Indian child with mongolian features. Head is brachycephalic. Eyes are obliquely set. Tongue is thick and coarse with many fissures running through it. Lips are fissured. Incisors are irregular, teeth are deficient in enamel and several are carious. Palate is high and narrow. Tonsils are large and cryptic. Ear lobes are attached. Skin and hair are dry and coarse, there is an excessive growth of hair on her back. Fingers are short and spatulate. Both feet are markedly pronated. Creases in soles and palms are very coarse. Joints are hyperextensible. Deep reflexes are diminished. Heart, lungs,

Fig 1 (Case 1)

Fig 2 (Case 2)

and abdominal organs are negative. Blood Wassermann, blood count, and urinalysis are negative

Her behavior is pleasant and agreeable at times, but when disturbed, appears very fearful, cries, and tries to leave the examiner. She does not respond to questions or commands, her main interest being in leaving the room. There seems to be no coherence between thoughts and actions

CASE 2 B B, male, age six, American Indian, I Q 36 (Fig 2). His father was a Seneca Indian and mother, Cattaraugus Indian, parents unmarried at time of patient's birth. Father died several years ago of typhoid fever. Mother was forty at time of patient's birth, having had one child (also a mongolian) a year previously, and two boys, by a different father, twenty and twenty-two years ago respectively. There is no history of early life except that the patient walked at about one year.

Physical examination Patient is a fairly well-developed, fairly well-nourished Indian child with mongolian features. Head is brachycephalic. Eyes are obliquely set. Cheeks are quite ruddy. Tongue is coarse with fissures through it. Lips are fissured also. Palate is normal. Tonsils are large and cryptic. Ears stand out prominently, left lobe attached. Skin is dry and smooth, hair is dry and coarse. Fingers are short and stubby. Creases are prominent on soles and palms. Feet are slightly pronated. Joints are hyperextensible. Deep reflexes are diminished. Heart, lungs, abdominal organs, and genitalia are negative. Blood

Wassermann, blood count, and urinalysis are negative.

Regarding behavior, the child is very pleasant and agreeable, obeying examiner in all respects. Does not talk except for a few mumbling, unintelligible words. Plays with examining instruments and is aware of his surroundings. There is virtually no insight and judgment present.

CASE 3 A B, male, died a year ago at the age of six of bronchopneumonia, American Indian, I Q 37.

Parental history same as for his brother (case 2). There is no history of early life except that he walked at the age of two.

Physical examination Before his death he was a fairly well-developed, well-nourished Indian boy with mongolian features. Ears were prominent, lobes attached. Eyes obliquely set, teeth spaced, skin smooth and dry. Heart, lungs, and abdominal organs were negative, testicles cryptorchid. Several experienced examiners thought him to be a mongolian at the time. In March 1935 he died of bronchopneumonia.

Summary

1 No cases of American Indian mongolism have been recorded in the literature.

2 Three such cases have been here presented.

BUNDLE BRANCH BLOCK

Diagnosis by Physical Signs

J A C GRAY, MD, *New York City*

Associate Attending Physician Central Neurological Hospital, Welfare Island

In the past few years there has been controversy in the literature as to the frequency and significance of certain physical signs in cases of bundle branch block. The signs in question are visible reduplication of the apex thrust of the heart, palpable reduplication of the apex thrust, and audible reduplication of the first apical sound. Where disagreement exists as to facts and their interpretation, review of the findings of others and report of the experience of still another clinic seems warranted.

To some extent, these signs have been associated with bundle branch block since the experiments of Eppinger and Rothberger¹ (1910) upon the results of section of the branches of the bundle of His in the dog. Following section of one bundle, they noted that the action of the ventricles became asynchronous and that a "gallop rhythm" appeared. Later in the same year Eppinger and Stoerck² reported similar physical signs in clinical cases of bundle branch block. Of five patients, two presented reduplications of the heart's action and one a gallop rhythm.

King³ in 1928 reported the successful clinical diagnosis of bundle branch block and the finding in nine cases of eight instances of visible reduplication of the apex thrust, seven of palpable reduplication, and six of audibly split first sound. There was also one instance of first apical sound followed by an asynchronous systolic murmur. He noted similar physical signs in patients without bundle branch block, recognized hypertension and aortic insufficiency as offering differential diagnostic problems, and suggested as diagnostic criteria the height of the blood pressure and the vigor of the heart's action—either hypertension or vigorous heart action rendering the diagnosis of bundle branch block unlikely.

King and McEachern,⁴ describing a

series of fifty cases of bundle branch block, stated that visible reduplication of the apex thrust was observed in forty-two of the cases, palpable reduplication in forty, and audibly split first apical sound in twenty-eight. Two distinct systolic murmurs were noted in six cases and separated first apical sound and systolic murmur in eight. They reported the successful clinical diagnosis of thirty-four cases out of forty in which the attempt was made, and concluded that bundle branch block should be recognized clinically in the majority of instances.

Recently, King⁵ has re-emphasized the frequency and diagnostic value of signs.

Hill,⁶ disagreeing with King, examined an unstated number of cases and found but one instance of bifid thrust and four of reduplicated first apical sound. He stated that bundle branch block is not recognizable on clinical grounds.

Lewis,⁷ employing apex cardiograms, phonocardiograms, and electrocardiograms, examined twenty cases of bundle branch block and three atypical cases. He found bifid thrust but once, but recorded reduplicated first sound five times and presystolic gallop nine times. Although he agreed with Hill that bundle branch block cannot be diagnosed without the electrocardiogram, he felt that the phenomena occurred too frequently in cases of bundle branch block to be regarded as coincidental, and concluded that the reduplications pertain to the types of heart disease in which bundle branch block is found rather than to that anomaly itself.

Lastly, Wolferth and Margolies,⁸ whose objective was to determine whether the "common type" of bundle branch block is in fact left bundle branch block, obtained apex cardiograms upon five cases of which three displayed bifid thrust, one presystolic thrust, and one a single thrust. They also found bifid thrust in normal controls.

From the foregoing it is apparent that reduplication of the heart's apex phenomena is found in some cases of bundle branch block, that the number of such findings differs in the experience of different observers, and that similar findings exist in the absence of bundle branch block.

The present study covers a period of thirty-two months and includes observations upon twenty-two cases of bundle branch block and upon six cases without bundle branch block which presented reduplications of all three of the heart's apex phenomena in systole.

All of the cases with bundle branch block were of the "common type" or left bundle branch block. All satisfy the criteria of Carter.⁹ Eighteen of these cases were examined in the Electrocardiographic Laboratory of the Central Neurological Hospital, four were seen elsewhere by the writer—three in the Medical Out Patient Department of the Roosevelt Hospital (New York City) and one in private practice through the courtesy of Dr. Martin DeForest Smith. The Central Neurological Hospital cases were derived, with few exceptions, from the New York City Home for the Aged and Infirm; the Roosevelt Hospital cases were derived from ordinary Out Patient Department practice. All of the patients were examined personally by the writer. The resident physicians of the Central Neurological Hospital cooperated in the study in so far as it concerned the patients in that institution. Six of the patients were examined clinically upon one occasion, nine upon two, and seven upon three or more occasions.

Apex cardiograms and phonocardiograms were not taken, the necessary apparatus not being available.

The essential facts regarding these cases is presented in Table I. Of the twenty-two cases, fourteen were men, eight women. The youngest patient was forty years of age, the oldest eighty-three. The average age was fifty-eight. (Owing to the small number of cases all calculations are expressed to the nearest integer.) Six cases were in each of the fifth, sixth, and seventh decades of life, three were in the eighth, and one in the ninth. Nine patients suffered from

arteriosclerotic heart disease alone, eleven from arteriosclerotic heart disease plus hypertension. Of these latter, the systolic blood pressure was in excess of 150 mm. of Hg in all instances and in excess of 200 mm. of Hg in four. One patient suffered from rheumatic heart disease, aortic insufficiency, functionally Class I. The type of heart disease in the remaining patient is open to question, although he probably belonged in the arteriosclerotic group.

Six patients had experienced attacks of coronary thrombosis shortly before examination as judged by the history, temperature, leukocytosis, and other evidence. Five complained essentially of the anginal syndrome, and six of the symptoms of congestive heart failure. In four patients, the cardiac status was secondary in importance to other diseases, respectively cerebral thrombosis, sarcoma of the liver, gonorrheal arthritis, and myxoma. One man considered himself to be in perfect health, a cardiac murmur detected when he applied for a position as porter at the hospital leading to complete examination with electrocardiography.

In this group of twenty-two cases of bundle branch block, visible reduplication of the apex thrust was observed in six instances, palpable reduplication in ten, and audible splitting of the first apical sound in eight. In two additional instances the combination of first apical sound plus asynchronous systolic murmur was noted. The action of the heart was vigorous in ten cases, average in ten, and obscured in two cases—in the one by obesity and in the other by extreme emphysema.

These reduplications tended either to be absent altogether in the given case or to occur in combination with one another. Eleven patients (half of the series) displayed no reduplications whatever. But one case displayed a single sign audibly split first sound, and this individual had a pronounced kyphotic deformity which rendered inspection and palpation unreliable. Five cases displayed two of the signs—four palpable plus audible reduplication, and one visible plus palpable. In five cases, all three signs were present.

While King and McEachern⁴ found visible reduplication most frequently,

Comment: Heart's action obscured in Case 1 by Obesity and in Case 13 by Emphysema. Primary Diagnoses in cases without cardiac symptomatology: Case 1 Cerebral Thrombosis. Case 4 Sarcoma of Liver. Case 5 Gonorrheal Arthritis. Case 20 Myxoma. Case 19 considered himself to be in perfect health.

palpable reduplication next, and audible reduplication least frequently, in the present cases palpation and auscultation each yielded an equal number of positive findings and inspection a lesser number. One possible reason for this is the fact that three of the four patients whose apex thrusts were palpably but not visibly reduplicated were women with large breasts.

In some of the cases the signs were inconstant. Thus in Case 12 the signs were not noted when the patient was admitted to the hospital but were fairly obvious when he was up and about the ward a few weeks later. In Case 15 all three signs were present when the patient was admitted and a clinical diagnosis of bundle branch block was correctly made. There-

after, however, during a period of a year during which the patient was repeatedly examined, the visible and palpable phenomena were in abeyance and the splitting of the first apical sound was but intermittently present. In Case 10 the signs were noted eight months before the onset of bundle branch block as judged by the electrocardiographic evidence.

In four of the cases which displayed the signs clinical diagnosis was correctly made. In the remaining seven the electrocardiogram had been taken and read before the writer or those cooperating in the study were able to examine the patient.

To summarize, in just half of a series of twenty-two cases of bundle branch

block one, two, or three of the heart's apex phenomena were reduplicated

During the period of the study, out of a total electrocardiographic material at the Central Neurological Hospital in excess of three hundred patients who did not have bundle branch block, four individuals were observed each of whom presented all three of the reduplications under discussion, and two additional instances were observed in the Roosevelt Hospital Out Patient Department which likewise presented differential diagnostic problems. There were other instances of split first sound at the apex noted, but since this finding is relatively common even in the healthy, such instances were not considered worth including in this study.

The six patients presenting all three reduplications in the absence of bundle branch block, four men and two women, ranged in age from forty-seven to seventy-seven (Table II). The average age was sixty-five. One patient was in the fifth decade of life, one in the sixth, one in the seventh, and three in the eighth. Four suffered from arteriosclerotic heart disease with hypertension, one from essential hypertension with uremia, and one from syphilis of the aorta with aortic insufficiency. With the exception of the last, all of the patients were markedly hypertensive, the systolic blood pressures being respectively 204, 264, 180, 260, and 190 mm of Hg. The syphilitic patient had a normal systolic pressure with a wide pulse pressure. One of the arteriosclerotic patients and the uremic patient complained of the anginal syndrome. Three of the patients came to examination

because of noncardiac complaints: cataracts, tuberculosis of the lungs, and cerebral arteriosclerosis. The syphilitic patient was in congestive heart failure when first seen.

Each of these individuals displayed visible and palpable reduplication of the heart's apex thrust and audible splitting of the first apical sound. The force of the heart's action was vigorous in five and average in one. The reduplications were constantly present and were easily elicited upon examination. Upon the basis of the signs, clinical diagnosis of bundle branch block was erroneously made in three cases.

Comparison of the two groups of cases indicates that the sex distribution and the years of life spanned by each is approximately the same, although the patients with bundle branch block were upon the average seven years the younger. From the point of view of etiology, arteriosclerosis is the most important factor in each group, having occurred in twenty (91%) of the cases with bundle branch block and in four (66%) of the cases without bundle branch block. One-half (50%) of the cases with bundle branch block were hypertensive whereas five (83%) of the other cases were hypertensive. Symptoms were much alike in the two groups except for the fact that coronary thrombosis had occurred recently in six of the cases with conduction disturbance, but in none of the cases without. Vigorous heart action was present in ten of the cases with bundle branch block and in five of the other cases (respectively 45 and 83%).

The most significant difference between

TABLE II

Comment: Primary Diagnoses in cases without cardiac symptomatology. Case 1: Cataracts, Case 4: Tuberculosis of the Lungs. Case 6: Cerebral Thrombosis. Case 2 suffered from Essential Hypertension with Uremia.

the two groups is the fact that whereas reduplications were found in eleven out of a total of twenty-two cases of bundle branch block, they were found in but six cases in a total electrocardiographic material of over three hundred cases without bundle branch block

If the results of the present investigation be contrasted with those of others, it will be seen that they correspond more closely to the results of King^{3,5} and of King and McEachern⁴ than to the results of other observers. From the findings of King and of King and McEachern, they differ in degree but not in kind. The percentage of positive findings in the present cases is less, but the nature of the findings is identical.

On the other hand, the percentage of cases here described which presented no reduplications (50%) is sufficiently great to prevent acceptance of their conclusion that the majority of cases of bundle branch block may be recognized clinically.

The question rises, do the reduplications ever justify the clinical diagnosis of bundle branch block in the particular case or do they merely suggest the presence of that anomaly on the basis of the fact that they are more common in bundle branch block than in any other condition?

Based upon the experience of this study, it is the opinion of the writer that the signs possess no more suggestive value, but that, given two or more of them, the diagnosis of bundle branch block is rather more than less likely to be correct. Further, upon the experience of this study, use of the height of the systolic blood pressure and the vigor of the heart's action as criteria to disentangle cases with conduction disturbance from cases without, is of little value. Six of the eleven cases displaying the reduplications were hypertensive, and three of them had systolic blood pressures in excess of 200 mm of Hg. Eight of the eleven cases had vigorous systolic thrust of the heart. But two of the eleven had at the same time normal blood pressure, average heart action and reduplications.

There is but one circumstance in which, having in mind the findings here recorded, the clinical diagnosis of bundle branch block would seem to be reasonably secure. Since none of the cases without bundle branch block which pre-

sented the reduplications had experienced attacks of coronary thrombosis and six of the cases with bundle branch block had, it would seem reasonable to infer that if a patient develops bifid apex thrust with or without reduplicated first apical sound following an episode of vascular occlusion, he has developed bundle branch block.

Summary

1 Twenty-two cases of bundle branch block were studied to determine the presence or absence of visible and palpable reduplication of the apex thrust of the heart and audible splitting of the first apical sound, or first sound followed by an asynchronous murmur.

2 Eleven cases presented none of the signs. One case presented a single sign, five presented two, and five all three signs.

3 From a material in excess of three hundred cases without bundle branch block but six were observed which had clinically indistinguishable signs. Upon the average, these patients were somewhat older than the patients with bundle branch block, and a greater percentage were hypertensive and had vigorous heart action.

4 While the results of the study differ in degree but not in kind from the findings of King and of King and McEachern, the difference is sufficiently great to prevent acceptance of their conclusion that the majority of cases of bundle branch block may be recognized clinically.

5 The conclusion is expressed that the reduplications in question strongly suggest the presence of bundle branch block but do not *per se* warrant that diagnosis.

6 Clinical diagnosis of bundle branch block is most likely to be correct in a case of coronary thrombosis which presents the reduplications.

THERMAL THERAPY IN CHRONIC DISEASE

RICHARD KOVACS M D, *New York City*

In the pathology of chronic disease, the most characteristic phenomenon is the apparent inability of the human engine to re-establish normal functional and structural conditions. Physical agents have played a role in the fight against chronic disease and infirmity since the early days of mankind and thermal agents have been in the forefront among them. The colonizing legions of the Roman Empire erected thermal establishments of a uniform pattern all over Europe and sufferers from chronic diseases became pilgrims to these and other hot spas. In the centuries of evolution since, thermal measures continued to be most popular for assisting the natural forces of restitution in the combating of chronic diseases. Clinical and experimental research and present day physical science have greatly enlarged their scope and effectiveness.

Physical Effects

The sources and forms of heat employed in modern therapeutics are manifold. No matter what form of heat is administered, its immediate effect is purely physical: a rise of temperature in the part to which heating is applied. The primary physical effect will vary according to the form of heat, its intensity, and length of application. It has been shown by Sonn  that with radiant heating maximum tolerance on the surface is 113.9°F , and on the under surface 117.8°F . With diathermy and short wave diathermy in animal experiments the following average rise in temperature was produced: joints, 8°F (Edstrom), stomach 1.3°F , pancreas, 4.5°F (Stewart and Boldyreff), orbit, 8.1°F (Moncrieff et al), pelvis of kidney, 2.1°F (Schliephake). Corresponding effects in human tissues were corroborated by many clinicians. General body temperature has been elevated with the newer methods of hyperpyrexia to 107°F .

According to the temperature law of Van't Hoff for every rise of 10°C the rate of oxidation is increased 2.5 times, and thus even temperature changes of tenths of degrees will influence cellular oxidations and exert marked effects on physiological processes.

Physiological Effects

The heat-regulating mechanism of the body endeavors to maintain a constant temperature and when heat is applied to a part from any external source, the vasomotor mechanism responds with an effort to dissipate the excess heat. There follows an active vasodilatation of the capillaries and a subsequent increase of arterial and venous circulation. Lewis¹ has shown that irritation of the skin releases a histamine-like substance which causes dilatation of the capillaries. This local hyperemia in turn results in an increase of the rate of removal of local tissue products and in stimulation of the local resistive forces, among these an increased phagocytosis.

An important therapeutic effect of local heating is that in mild dosage it acts as a sedative on irritative conditions of sensory and motor nerves. Hence the relief given by thermal measures in many painful sensory conditions and in cramps and spasm.

When heating is applied at sufficient intensity to a large part of the body or if heat loss from the body is prevented, a rise of body temperature and general changes occur. There is an increase of the circulatory rate and of metabolism, a rise in blood volume and oxygen consumption, and a change in the urine, blood, and sweat to the alkaline side. A summary of the complex local and general effects of heating can be found in the writings of Bazett² and other physiologists.

The attenuation or killing of heat sensitive organisms is another valuable effect

Read before the Medical Society of the County of New York, December 16, 1935, the Atlantic County Medical Society, March 13, 1936, and the Medical Society of the County of Saratoga, June 4, 1936.

of local and general heating. The gonococcus is the most frequently encountered heat labile organisms, recent fever therapy work by the Rochester group established that the thermal death time of various strains of gonococci at 41.5°C varies from six to twenty-seven hours in vitro, other investigators showed that an average of 107.6°C body temperature for six hours was destructive on *trepanoma pallidum* in experimental syphilis.

Artificial fever has become a recognized measure for increasing the protective and defensive mechanism of the body in many chronic diseases. Its presumable clinical benefits have been summed up recently by Hench, Slocumb, and Popp^a of the Mayo Clinic as follows:

- 1 A direct bacteriolytic or bacteriostatic effect due to the influence of heat itself on bacteria (without necessarily implying formation of immune bodies)

- 2 An indirect bacteriolytic or bacteriostatic effect resulting from increasing formation or mobilization of immune bodies

- 3 A local effect from vasodilatation, providing an augmented blood supply to inflamed tissues

- 4 A general effect from the heightened metabolism incident to fever

Forms of Heating

It is evident that the physical and physiological effects of heating on the structures of the body will vary not only according to the form but also according to the intensity and duration of heating. There is a certain interchangeability between sources of heating, and, by varying the other factors, similar effects may be produced by different methods. We are still far from the ideal of exact dosages to meet the variety of conditions and most of the technics established so far rest on empirical basis only.

Generally speaking, conductive sources of heating—hot compresses, hot poultices, hot water bottles—are least effective, because their source of heating is not constant, their heat penetration is limited and furthermore, they are cumbersome and often unbearable on account of the pressure exerted. Hot water baths and hot air "baking" are more convenient sources for heating the skin and superficial tissues but their penetrating effect is very

limited, with surface temperatures which can be safely tolerated, the deep lying tissues dissipate heat at a faster rate than it can be conducted to them. Hot whirlpool baths offer a useful combination of surface heating and mild mechanical stimulation. Radiant sources of heating—heat lamps and infra-red heating units—have come into fairly general use on account of the simplicity and safety of their application. They are also much more efficient in heat penetration because their rays penetrate the entire thickness of the skin, part of subcutaneous tissue, superficial strata of muscles, and accessibly located tendons and bones. Many unnecessary burns in recent years could have been prevented had neophytes abstained from applying diathermy without rhyme or reason for many of the conditions where heat radiation is just as effective and involves only a minimum of risk.

Diathermy or the passage of high frequency current through a part results in its conversion into heat. Because of the gradual introduction of electrical energy, there is no such marked reflex action of the heat-regulating mechanism as with external forms of heating and the placing of metal electrodes directly over the heated parts also prevents appreciable cooling by evaporation. Diathermy enables penetrating heating in a host of chronic inflammatory conditions where the pathological changes are located in the deeper parts. Maximum heating will always be generated at the site of greatest current density and this as a rule occurs near the electrodes and is proportionately less in the depth. The old notion that greatest heat effect in diathermy takes place in the center between the electrodes has long been disproven.

Short wave and ultra-short wave diathermy is a recent method of heating in which the body or a part of it is placed in a "condenser field" consisting of metal plates separated from the skin by an insulating layer of air, rubber or glass. These electrodes are charged by oscillations at radio frequency and it has been shown that there is more heat production in the depth by this method. As with every new method, commercialized propaganda makes many unwarranted claims for short wave diathermy, while its appli-

cation is undoubtedly simpler, the control of dosage is crude while the new technic and appliances and the lack of standardization of its apparatus rather increase the potentialities of accidents. No convincing proof has been brought yet that the clinical results produced are different from those of conventional diathermy.

For general body heating any of the enumerated methods may serve. Hot baths and electric light cabinets have been in use for some time for milder degrees of general heating. The modern interest in artificial fever led to the development of efficient general thermal methods. Physical agents have the advantage over the other fever methods in that they are always available, that the febrile reaction is under complete control and that the procedure is sterile. Fairly uniform results have been achieved by different methods, such as hot baths, hot vapor, electric blankets, hot air or infrared cabinets, general diathermy, and short wave diathermy. In these procedures, heat energy sufficient to overcome the heat-regulating mechanism of the body is employed while suitable insulation prevents heat loss by evaporation.

Therapeutic Uses

Thermal measures in the treatment of chronic diseases are employed either for treating the causative factor or for relieving the symptoms or sequelae. In many conditions, maximum benefit will only ensue if heat is combined with other physical measures. It is also evident that in the majority of cases physical therapy is only part of the treatment and supports rather than replaces other indicated measures.

The most important group among chronic diseases in which thermal measures form an indispensable part of treatment are chronic arthritis and rheumatoid conditions. "Rheumatic exudations are smouldering foci of disease, and heat, properly applied, often affects their absorption."⁴

Heat therapy in chronic arthritis is applied from two distinct angles. General or systemic heating is part of a "constitutional" therapy. By stimulating general circulation and increasing body metabolism it ameliorates the arthritic diathesis

and though local changes are only indirectly effected, in many instances following general heat-treatment there is a decrease of pain and swelling in all affected parts. Local heat-treatment has as its object the increase of local blood and lymph circulation and local tissue metabolism, the promotion of resorption and restoration of function. An even more important effect of suitable local thermal application is the relief of pain, the symptom which is the most bothersome and most depressing, next to stiffness and limitation of motion. In selecting thermal measures the type of arthritis and the constitution of the patient has to be taken into consideration. Generally speaking, robust patients of the osteoarthritic type respond well to both local and general heating while in the rheumatoid type of arthritis and in asthenic patients, vigorous heat measures often prove exhausting.

The simplest and most easily available thermal measure for general treatment of chronic arthritis is the hot bath. It may be used in the home at a temperature from 96 to 102° F. two to three times a week from five minutes to half an hour. A series of hot baths, alternated with or followed by suitable local treatment, is usually the backbone of physical treatment of chronic arthritis in health resorts. In physicians' offices, light baths from high wattage incandescent lamps and, in institutions, electric light cabinet baths prove useful. Hyperpyrexia by various methods has been extensively employed in recent years, in the majority of cases of rheumatoid arthritis it has not given encouraging results.

Local heating in chronic arthritis is perhaps the most dependable standby. For fairly efficient routine treatment in the home and in the office, infrared and luminous heat reflectors have largely replaced cumbersome "baking" boxes. Diathermy is of specific value in osteoarthritis localized to one or two large joints or to the spine, also in the frequent bilateral knee involvement in middle-aged women. In rheumatoid arthritis diathermy has only a limited value.

In non-articular manifestations of the rheumatic syndrome, characterized by chronic inflammatory connective tissue changes in muscles, tendons, bursae and

nerve sheaths—collectively designated as fibrositis—the same principles of thermal therapy apply. Possible foci of infection must be attacked, simultaneously, mild general heating for the increase of elimination and the raising of general metabolism may be employed while in all cases local heating serves for relief of pain and resorption of inflammatory thickening. This is the scheme of effective treatment of myositis, bursitis, tenosynovitis, and many forms of neuritis. Additional local mechanical measures are at times indispensable but give full benefit only when preceded by heat.

Gonorrheal infection, both acute and chronic, has proven to be perhaps the most successful object of thermal therapy, especially since the advent of hyperpyrexia. Local diathermy applied, as a rule, to the focus of gonorrheal infection, the cervix, urethra, prostate or seminal vesicles, at other times to the secondarily affected joints, produces good results in a fairly large percentage of cases. By hyperpyrexia, practically all cases of gonorrheal arthritis which are resistant to focal and local diathermy can be cleared up. Bierman and Horowitz⁵ have shown that the elevation of systemic temperature to 105–106°, combined with raising the pelvic temperature to 110–112°, gives brilliant results in gonorrheal infections of the pelvis. By determining the thermal death time of gonorrheal strains in the individual the ideal of a single fever treatment of sufficient length is attempted, resulting in a bacteriological cure and an immediate subsidence of all clinical symptoms.

Fever therapy of neurosyphilis and possibly of early syphilis has opened up an important new field. In general paresis, tabes and taboparesis and central nervous system syphilis results by physical fever methods similar or better than those with malarial inoculations are on record. Suggestive evidence is offered by Simpson⁶ that in early syphilis and resistant seropositive syphilis, combined fever-chemotherapy gives superior results. There are reports of similar findings in other late manifestations of syphilis, notably ocular complications. Encouraging results have been shown also in early cases of multiple sclerosis.

In chronic inflammations of the organs of the abdomen, heat therapy, especially

in the form of diathermy has become a recognized standby of treatment. Chronic inflammations of the gall-bladder and ducts and of the female organs, peritoneal adhesions following gastric and intestinal conditions or operations, strictures of the rectum, have all proved grateful objects for treatment by diathermy. The antispasmodic action of deep heating has given good clinical results in spastic conditions of the stomach, gall-bladder, intestines, and pelvis of the kidney, as well as in gastric neuroses and in congestive or inflammatory types of dysmenorrhea.

In chronic circulatory disorders there is a large field for thermal therapy. Cardiac diathermy enhances the tone of the heart muscle, improves the subjective signs of its vasomotor disturbances and thus offers valuable aid in treating chronic coronary disease. In essential hypertension autocondensation, a form of general high frequency treatment has proven useful but exerts no specific effects. In peripheral circulatory disturbances of the spastic type, such as Raynaud's disease and intermittent claudication, moderate local heating by whirlpool baths or by diathermy, often gives marked symptomatic relief. The same treatment is useful in early stages of arteriosclerosis and thromboangitis obliterans, in advanced cases it is better to employ only mild external heating from radiant sources kept around 94° F, regulated according to individual tolerance and applied practically continuously.

One could go on enumerating the therapeutic uses of heating measures in chronic disease occurring in practically every part of the body. It is a fact that thermal therapy has become the most important routine in treating chronic inflammatory conditions, when the natural forces of resolution appear to be lagging.

Summary

- 1 In the treatment of chronic disease by physical measures, heat is the most important single agent.

- 2 The extent of physical and physiological effects of thermal measures depends on their form and technic of application.

- 3 The therapeutic effects of heating are based upon its physiological action on ac-

celerating circulation, increasing metabolism, allaying sensory and motor nerve irritation, and affecting heat sensitive bacteria

4 The largest sphere of usefulness of heat therapy is in promoting resolution

in chronic inflammatory conditions. Fever therapy by thermal measures is of specific value in gonorrheal infections resisting ordinary treatment and in neurosyphilis

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, MD, DR PH, New York City

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine

Tamed

I would not like to convey the impression that psychotherapy in the transition cases is always an easy work. But sometimes we encounter fewer obstacles and our road is smooth.

The following case was successful from the beginning.

A girl of twenty-three suffered from a combination of psychoneurosis and a mild form of manic depressive psychosis. From her first steps in babyhood she remembered her father and mother quarreling and fighting. Each time they separated the child felt a great relief and the final parting was a natural outcome of a life full of ugly feuds. The father drank heavily and spent outside all the money he earned. The mother was an habitual complainer and nagger who could not get along with anybody. Our patient went to live with her grandmother, a widow with a small, but sufficient income.

Marital, parental conflicts always leave some mental scars in children, often causing maladjustment or definite mental disorder. The effect upon this girl of the parents' ceaseless enmity and war was particularly bad. To that was added the humiliating fact that her face was covered with acne.

Acne and superfluous facial hair in young women, acne and falling hair in young men are great sources of irritation especially in those who are unable to accept their fate calmly and cannot be resigned to it. In abnormal individuals those conditions are fuel to a vivid fire and make the victims suffer intensely.

Our patient, when first seen, was like a wild animal. Although she had come to the clinic alone, she didn't care about anything the doctor said to her. She looked away from his face and followed her own thoughts. She cried continuously and talked loud and angrily, enumerating her misfortunes. Her hair was dishevelled, her dress unclean and neglectfully slipped on, her shoes unlaced, her entire appearance untidy. Her general odor betrayed that her body had forgotten the use of water. Any remark was met with a quick and aggressive volley of words aimed at disarming any reply. She proclaimed her situation as hopeless and there was no use in trying to improve it. Nobody was interested in her, everybody despised her. She had an immediate objection to anything that contained a praise or a hint to a possible future improvement. To call her a smart or intelligent girl was a daring and almost dangerous action.

And yet there was a moment when she lifted her head and a little later a second in which she had a fleeting smile. That happened when a sensitive cord was stricken, when the "eternal feminine" ambivalence, of which even she had a spark left, was touched. Something or other was said about the possibility of her being good looking if she desired it, or something similar.

Then she began to listen more than she talked. She seemed surprised and partly convinced. So there was a person in this wide world who had some real sympathy

for her. She was no longer beaten and hounded, whether in reality or in her imagination.

Soon she was absorbed in my talk and later, when entirely subdued, she was asked about her childhood and her past in general and she answered in a rational way.

At the end of the first consultation she was conquered. She smiled and said "Gee, I feel better already."

When she came again a list of instructions was given to her concerning food, sleep, bath, walk outdoors, and her acne.

Then a long interval was left. Her next

consultation was three weeks later.

The change was manifest. Her hair was combed, her clothes, though poor, were brushed and properly buttoned, her shoes were well-laced and shined. She was quiet and met the doctor's glance frankly. Her acne had greatly improved.

She said "Everybody is telling me that I am much better and I feel it myself."

She continued to improve and regained her position in life. When I learned, within a few weeks, that she had gone, for the first time, to a dance, I regarded her as cured.

Doubtful Heredity

Wherever there is a psychopath in a family—and how many families, alas, are free from them—every close relative expects some mental disturbance. The physician must do his best to lay this ghost.

A young student began his story by saying "My mother's brother died from insanity and, therefore, it is self-understood that I too must be mentally ill."

At first I tried to find out all about his uncle's illness.

He answered my questions with precision and went into all the details. It seems that the old man, who had always been the family tyrant, toward the end of his life, had put many objects aside to be "buried with him" and also desired some of his relatives, including the present patient, to accompany him into "the other world." Whether he had heard of the ancient Egyptians or not, like them he needed his "ushabt" or slaves so that there be no break in ministering to his wants after death. And his heavy ghostly paw was still weighing on his nephew's shoulder and in his mind in the form of the fear of a so-called heredity.

The young man looked around in the office and everything frightened him.

"What is behind those velvet curtains?"

he asked.

At the second visit a book on neurology, out of alignment on the shelf, stared at him so with its large gilt lettering and he remarked that it had been there, the first time, at exactly the same place.

He kept on repeating that he was doomed and he did not know why he came.

But he was extremely surprised to hear that the facts of heredity were not at all sure, that in science we judge by actual finding and not by mere theory, that real scientists mix some skepticism in all their knowledge and that the more one knows the less certain he is. And he appeared shocked when told that to accept heredity as a certainty in an individual case amounted to superstition.

"Doctor!" he exclaimed.

"Yes, sir, a scientific superstition."

Moreover, his own parents were well and so were his brother and sister, he said after a silence.

The third time he left bewildered. But the results were good and quicker than expected. Within a few days he returned beaming and genial and assured the doctor that now he was entirely cured. He had finally corrected his error that some sort of insanity must fatally come.

Superior or Inferior?

A successful sales agent felt "his decline" coming. He was suffering more and more from what he called "an inferiority complex." He could not approach people with his usual *aplomb*. The truth was, another traveling salesman with the same firm was doing better than our patient.

Upon further analysis it became evident that his inferiority complex was not at all a sign of true inferiority, but, on the contrary, he was superior to the average people of his kind and, what is more, he was perfectly aware of it. The trouble was, he

did not dare to appear as he really was, to show his qualities, for fear of ridicule. He avoided making use of his originality because his colleagues would laugh at him. Therefore, he was not giving, lately, the best in him and, naturally, he was losing ground and falling behind.

As soon as he understood this situation he changed his point of view and discontinued the consultations. When met later he said "I was cured within a short time, I went out and worked and did well."

THE MEDICAL WITNESS

HON MEIER STEINBRINK, *New York City*

Justice of the Supreme Court of the State of New York

More than a century ago, a teacher at Columbia University defined medical jurisprudence "as that science which applies the principles and practice of the different branches of medicine to the elucidation of doubtful questions in courts of justice"

From time immemorial, courts of law have freely invoked the assistance of men skilled in subjects not of common knowledge. There is frequent allusion to the use of experts in the Roman law and likewise in the earlier common law reports. In certain urban communities of England, as early as the fourteenth century, special qualified jurors were called in when necessary to pass on questions requiring peculiar skill. In time, skilled persons were summoned to the advice of the court. Originally the jury proceeded to a verdict without the benefit of witnesses. They simply went after facts in their own way. It was not until the middle of the fifteenth century that the practice of examining witnesses became well-settled and it was not until some time later that compulsory process was made available. One of the rules of evidence hammered out of the early trials was that the testimony of a witness shall be limited to facts, not to opinions or conclusions from facts. It was for the jury to draw conclusions from the facts presented. But as this rule took shape an exception was made in the case of experts who were permitted to express their opinions. There is reference in the English reports to medical testimony as early as 1620.

In the case of *Alsop v Bowtrell* (Crow Jac 541) certain physicians testified in a case involving the legitimacy of a child that it might well be that a woman bore a child forty weeks and nine days after her husband's death and yet be his child, for the birth might be delayed by ill-usage and lack of strength.

In 1665, in the *Witches* case, a physi-

cian was of the opinion that the accused were witches, and elaborated his opinion by an explanation of the fits to which they were subject.

Rex v Pembroke was tried in 1678. Pembroke was charged with murder and there was some question as to the real cause of the deceased's death. Physicians called by both sides testified both as to the causes of certain symptoms observed upon an autopsy they had seen, and as to the general proposition whether a man can die of wounds without fever.

Another case reported the following year was *Rex v Greene*. There a physician called for the prosecution testified that the deceased could not have died from certain wounds upon his body as there was no evidence of blood and therefore that he must have died of strangulation.

In 1699, in *Spencer Cowper's* case, the question was whether the deceased had been drowned. Certain surgeons had testified that they had examined the body and found no water in it, so that it must have been dead when it entered the water.

From this small beginning, the participation of doctors in the administration of justice has grown to a point where it is almost unlimited.

While this graduate fortnight of yours is devoted to the subject of trauma, occupational diseases, and hazards, yet this by no means marks the bounds by which you function in the court room. There are few cases in which we do not in some form or other turn to the medical witness. Criminal cases innumerable flock to mind—murder, poisoning, drowning, abortion.

From the most recent compilations of the commission on the administration of justice, we learn that no less than seventy-five per cent of the cases tried in the Supreme Court of this state involve injuries to persons claimed to have been

Address delivered before the Medical Society of the County of New York, October 26, 1936

eghlytly inflicted In the proof of such cases, medical testimony is rarely omitted To these should be added numerous cases in which injuries were claimed to have been intentionally inflicted

In matrimonial actions, the services of our profession are frequently used to assist the court in passing on such questions as the existence of disease and mental disorder in one of the parties to the marriage either before or during marriage Also whether a party to the marriage is sexually impotent or sterile

Your services are likewise freely used in cases involving questioned paternity which may arise in filiation proceedings, actions for divorce, actions for criminal assault, and the like

Malpractice cases are wholly dependent on medical proof

In will contests and in incompetency proceedings, we turn unhesitatingly to you for guidance and for aid A large bulk of the proof in workmen's compensation proceedings is medical

It can thus be seen that in the greater number of cases coming before the court, medical testimony must of necessity play a dominant and often a decisive role It is for that reason that our method of eliciting medical testimony must be subjected to the closest scrutiny and any defect, no matter how slight, be exposed and, by cooperative action between your profession and mine, corrected

Medicine is a science wherein divided respected opinion is not uncommon We dare not hope for infallibility in medical experts—at least not until every diagnosis is confirmed by subsequent developments or by autopsies The layman's tendency, therefore, to place more credence in tangible facts than in opinions is not difficult to understand Nor can we fail to appreciate his suspicion of divided expert opinion

These are the conditions which face the medical expert witness at the very outset and because of them he must bend every effort towards the discharge of his duties in a manner that will reflect credit on himself and the great profession which he represents He should never forget that his testimony is given to instruct and inform the court and jury with regard to some vital point in issue, and it is no

less important that *he* approach the case wholly uncommitted in opinion, than that the jurors should Any individual who contributes even in the slightest to a relaxation of public confidence in the administration of justice commits a serious transgression against society A physician who, under the impetus of a more or less substantial retainer refuses to abide by the rules laid down for us by the highest courts, cannot avoid the realization that his conduct inflicts grave harm, not alone upon his profession, but upon one of the most vital forces that make for good government—the true administration of justice Perjury is a crime, but it is no less wrong for a physician to exaggerate or minimize symptoms and conditions described, to wilfully relate a partial truth which prevents an accurate appraisal by the jury or to confuse the issue by introducing factors which have no scientific relevance to the subject litigated As a member of a learned and public calling, he must be governed by rules which transcend the distinction between legal and moral wrongs Such is the responsibility of the medical witness

Under our present system, each party to a law suit calls witnesses to prove or disprove some issue in the case The rules governing the subjects on which experts may testify and prescribing the qualifications of experts are matters of law, but whether a witness offered as an expert has those qualifications is a question of fact to be decided by the judge The trial judge enjoys considerable latitude in the exercise of his judgment and his ruling is conclusive unless manifestly erroneous as a matter of law The mere fact that the witness is a physician does not in and of itself qualify him to express an opinion on some highly specialized branch of medicine By study and experience he must have acquired peculiar skill in the subject on which he is called to testify When his qualifications are established, he is questioned by the counsel who retained him Unless he can testify as to the facts upon the basis of actual observation, he is generally asked a hypothetical question, in which is incorporated at great length all of the relevant facts in evidence After expressing his opinion, which is rarely if ever unsatisfac-

tory to the questioner and his client, he is turned over to the opposite side for cross-examination. The function of the cross-examiner is to elicit from the witness a modification of the opinion expressed on direct examination, or to discredit the direct testimony.

In a typical case, physicians are arrayed on opposite sides of the law suit. Each is given the same set of facts and each is asked to express an opinion. Although the physicians may command equal eminence in their profession, their opinions are too often wholly irreconcilable with the anomalous result that the jury is required to reach a verdict where the physicians disagree. The result is obviously anomalous because the jury, consisting of men possessing no peculiar learning or skill in medicine, are left to decide causes in which the experts are called to aid them. This condition has met with almost universal condemnation and, in all frankness, lends considerable support to the general disrepute in which experts are held and their testimony disparaged.

Justice Curtiss, of the United States Supreme Court, observed in one of his opinions:

I believe the experience of all concerned in the administration of justice tends to the conclusion that this species of evidence is less satisfactory than any other, and it is a common remark that when there is any room for a difference of opinion experts in about equal numbers will generally be found testifying on each side. (*Wilkinson v. Greeley*, 1 Curtis (U.S.) 439, Fed. Cases 17,672.)

Justice Miller, of the same court, said:

My own experience, both in the local courts and in the Supreme Court of the United States, is that whenever the matter in contest involves an immense sum in value and when the question turns mainly on an opinion of experts, there is no difficulty in introducing any amount of them on either side. (*Middling Purifier Co. v. Christian*, 4 Dill, 448, at 459.)

In the famous trial of Palmer in England in 1856 for the murder of Cook by poisoning, more than a dozen medical men and chemists testified with great positiveness but in direct opposition to each other. Lord Chief Justice Campbell, in charging the jury said:

With regard to the medical witnesses, I must observe that, although there were among them gentlemen of high honor, consummate integrity and profound scientific knowledge, who came here with a sincere wish to speak the truth, there were also gentlemen whose object was to secure an acquittal of the prisoner. It is, in my opinion, indispensable to the administration of justice, that a witness should not be turned into an advocate nor an advocate into a witness. (11 Harv. Law Review, 170.)

Since expert testimony, as an aid to the jury, is indispensable, we must pause to inquire into the causes that produce the mischief and to take cooperative steps in broad comprehensive reform. A quarter of a century ago a committee on the regulation of the introduction of medical expert testimony submitted a report to the New York State Bar Association, in which they classified the existing evils as follows:

First—Want of satisfactory standards of expertness with its result of inviting the testimony of charlatans.

Second—The partisan conflicting and hence unreliable character of the evidence often given by so-called expert witnesses.

Third—The prolongation of trials and consequent increase of expense on account of the number of witnesses.

Fourth—The confusing effect on juries of the contradictory testimony of expert witnesses of apparently equal standing, having the same opportunity for acquiring knowledge of the facts on which their conflicting opinions are predicated.

Fifth—The lack of scruple upon the part of some members of the Bar in countenancing the hiring by their clients of unprincipled self-styled experts to support causes by specious and untruthful testimony.

Sixth—An unfortunate tendency upon the part of some trial judges to permit incompetent so-called medical experts to testify to opinions predicated upon widely unrelated facts and under oath to express views which are but the speculative vagaries of ill-formed minds.

To these may be added contingent fee payment to the expert, the fact that wealthy litigants are able to overawe a jury by a mass of expert testimony which the less fortunate litigant is unable to match, and the requirement of the hypothetical question.

Let us consider for a moment legal insanity as a defense in criminal law. Expert testimony in this connection has very often become a shameless mockery. Numerous specialists are called, large sums of money expended, trials protracted sometimes for weeks, on a simple issue as to whether the accused was insane at the time of the commission of the act. The defense is very often employed when there is no other avenue of escape, and generally in a case where no one would have remotely suspected the accused of insanity were it not for the exigencies of the case.

Psychiatrists, alienists, and other specialists in mental diseases, eminent in their fields and respected in the community, do not hesitate to sell themselves, even if, in doing so, a dangerous criminal succeeds in escaping the penalty which the law prescribes.

The basic evil is the personnel of the witnesses and the attorneys who cooperate in the deception and, as I touched on a short while ago, the anomaly of setting expert against expert, and thereby negating the testimony of all.

The hypothetical question has long been the subject of considerable comment. This form of question assumes the existence of facts recited by the questioning counsel. The facts assumed are only those which the court deems fairly established by the proof, and upon the basis of them the expert is asked whether he is able to form an opinion. If he is, he is asked to state his opinion. While the hypothetical question appears to be a perfectly logical and perhaps necessary means of extracting an expert opinion, unfortunately it often leads to a confusion rather than to a clarification of the issues. While the scope of the question may be kept within bounds, it is often exceedingly difficult for the court to confine the questions to those facts which the jury ought reasonably to find. If the jury fails to find some pertinent fact embodied in the question, there remains no force to the opinion, and the jury, left to its own resources, decides the case in complete disregard of the medical opinion. After a long, involved, and tedious hypothetical question, the answer is invariably an opinion favorable to the party by whom the expert is retained. There are

some who would do away with this form of question. Prof Wigmore said in discussing the subject: "The hypothetical question, misused by the clumsy and abused by the clever, has in practice led to an intolerable obstruction of truth."

A contested will case was recently tried in this state, in which a hypothetical question was propounded to three experts for each side. The two questions together consisted of six thousand words and occupied more than four hours in the reading. The effect of such questions on the jury is readily imagined. The difficulty is that while this form of question is subject to abuse and does in fact often retard the search for truth, it is still the only method by which the jury can avoid abdication of its powers as fact finders to witnesses who, though experts in their calling, are nevertheless no more qualified to find facts than the jury itself. If the expert were permitted to express his general views without indicating the facts upon which they are based, he would be usurping the function of the jury for, to accept the opinion, the jury must accept as found all the facts underlying it.

The solution, if any, does not require a complete rooting out of this type of question, but rests rather with an alert and well-equipped bench and bar whose duty it is to avoid and prevent dishonest and ineptly worded hypothetical questions.

The fact that experts are retained by the parties to the litigation and are compensated by them is one of the main sources of difficulty. Testimony under such circumstances without a taint of prejudice is a result devoutly to be wished but rarely achieved. The position of the expert is that really of participant in the law suit. That he so regards himself to a degree at least and that, in consequence, controversial feelings are aroused, is not unexpected. Some years ago, Dr. Edward P. Sloan, president of the Illinois State Board of Health, and president of the Illinois State Medical Society, made the following statement:

It is needless to say that any diagnostician can make a diagnosis with some certainty when aided by his regular assistants. Only by having the patient in a favorable environment and under conditions that are favorable to good work, and with sufficient assistance, can any diagnostician whose

sincere object is to arrive at the actual facts, make a diagnosis and give an opinion with regard to mental and physical states in obscure or disputed cases that is worthy of confidence or that should be given place in any proper legal proceeding. Without a correct diagnosis the medical expert is a false witness.

But it is unfortunately true that under present conditions in American courts, these conditions of securing correct and impartial judgments by the medical expert witnesses are sadly lacking. Approaching the subject from the partisan standpoint with a necessarily biased mind which the medical expert must do, precludes the formation of a correct judicial opinion. (Si-De-Ka Quarterly, April 1923.)

The vice has become specialized in the sense that daily in our courts we find physicians invariably appearing either on the plaintiff's side alone or on the defendant's side alone. They are labelled "plaintiff's expert" and "defendant's expert." The "plaintiff's expert" magnifies the injuries and symptoms, while the "defendant's expert" dismisses as negligible. It is not uncommon for doctors to accept general retainers from railroad companies and insurance companies and from lawyers whose practice it is to represent plaintiffs in negligence actions. No matter how honest the individual, the danger of having his judgment colored by the size of the retainer and his mode of thinking influenced by the side which he invariably takes, is manifest. This condition can be corrected in part at least by the exposition of a clear definition of the moral standards of a physician testifying under oath in the court room, by insistence that he state his opinions fairly and fully, without bias and without regard to the side that calls him, by taking a forceful position that any deviation from this standard involves a serious breach in professional ethics, to be dealt with as such.

I have briefly touched on some of the conditions which bring disrepute to your profession and on mine. Remedial measures have been suggested. Some are of the belief that the chief fault lies with the caliber of lawyers and doctors who collaborate in the court room. Undoubtedly the vices today inherent in expert medical testimony will vanish when all of the participants are beyond reproach. While I am certain that neither the medical

societies nor the bar associations will relax their vigilance in purging from the ranks those who bring discredit on the professions which they represent, yet the difficulties which beset their paths are as familiar to you as they are to me, and short of the millennium a complete purge is too much to expect.

Recognizing that fact, we must bestir ourselves rather to attack and revise the system that permits these abuses to continue. Some have suggested a subsidiary jury of experts. A reform of this nature would require a separate jury for each specialized field of medicine since the opinion of an alienist would have little value as to the existence of some disease unconnected with his specialty, and so on down the line. This will result in numerous subsidiary juries with the additional expense involved and with the difficulties attending their selection.

Furthermore, there is always the possibility that experts may disagree among themselves, thus weakening the force of their opinions. Finally, there is a serious question whether parties can be compelled to relinquish their right to adduce whatever proof they deem essential to their case.

A more practical remedy, in my opinion, is that embodied in the report of the Commission on the Administration of Justice in New York State, in the form of proposed legislation. It reads as follows:

Whenever it shall be made to appear in an action pending before the court, that expert evidence is, or will be required, the court may on motion of any party, or on its own motion, appoint one or more experts to investigate and testify at the trial of the action relative to the matter or matters as to which such expert evidence is or will be required.

The court shall fix the compensation of such expert or experts and shall determine the proportion in which the compensation shall be paid by the parties. The amount so paid by any party shall be taxed and allowed in like manner as other costs in the event that he should become entitled to costs in the action.

An expert so appointed shall file a report with the court, and furnish a copy to each of the parties but the report shall not be admissible in evidence.

The expert may be called by the court, or

may be called and examined by any party to the action, and he shall be subject to examination and objection as to his competence and qualification as an expert and as to his bias and may be cross-examined by the several parties to the action in such order as the court may direct.

When such witness is called and examined by the court, the several parties shall have the same right to object to the questions asked and the evidence adduced as though such witness were called and examined by an adverse party.

The court may at any time before the trial or during the trial limit the number of expert witnesses to be called by any party.

Similar provisions for expert testimony have been adopted in England and in California, and are under consideration in several other states.

The best feature of the proposed reform will be its tendency to avoid partisan conflicts now common among experts, and perhaps encourage reputable physicians to await invitation by the court rather than to accept private retainers. But no amount of legislation, no matter how nobly inspired, can accomplish its purpose without the whole-hearted cooperation of our professions, unless all our resources are brought to bear on the problem, unless we accept the responsibility that is plainly ours to extirpate from our midst the subservient forces much as you surgeons would sever the cancerous tissue from the healthy.

I have spoken of your duty. Now a word with regard to your rights. Like any other person subject to the jurisdiction of the court, a physician must respond to a subpoena. He is amenable to this compulsory process regardless of whether he is called to testify as to facts observed or to offer an expert opinion. If he is called in the former capacity, he is not entitled to compensation beyond the statutory fee of any witness. This rule is founded on the theory that in the interests of justice, everyone is under a public duty to testify as to facts within his personal knowledge. This rule, however, does not apply, at least not in the State of New York, to persons giving expert testimony. They are entitled to compensation on the theory that their expert technical knowledge, obtained after years of close application to some special subject, constitutes their stock in trade which they

should not be required to give away for the asking. While this is the rule in New York State, the weight of authority in other states inclines to the view that an expert witness is not entitled to demand extra compensation before testifying, although his testimony may have required professional study, learning or skill. In those states, the courts take the view that the social interest which imposes on all citizens the obligation to testify in aid of the ascertainment of the truth, transcends the inconvenience to which experts are subject. Valid arguments may be presented on both sides of this issue, but my own opinion is that an expert should no more be required to endow benefits on litigants without compensation than any business man should be required to relinquish his physical assets without being paid therefor. But even in this state the right to compensation is waived unless claim for it is made before the expert testimony is given.

Before closing, may I presume upon your attention for a few moments longer to suggest the conduct by which, in my opinion, you should be governed on the witness stand. Before coming into court, insist upon the fullest details concerning the subject upon which you are called to testify. Refresh your recollection concerning names, dates, and places that may be pertinent. Bring with you whatever memoranda you may have to fortify your memory. Refamiliarize yourself with the general subject and come prepared to submit to a searching cross-examination. In delivering your testimony, express only those opinions which you honestly believe and which you are prepared to defend to the last ditch. Do not play the part of an advocate. Forget for the time being the party by whom you were called and make every effort to rid yourself of any bias or prejudice that may unconsciously have crept into your thinking. Weigh the questions put to you with care and do not answer until you are certain that you understand them. Do not permit yourself to become embroiled in a dispute with the examining attorney nor to become flustered by the tactics employed by him, for this very often is the very result he is seeking to achieve when no other method of attack is available.

Act modestly and speak in a conversational tone, addressing your remarks so that every member of the jury can hear what you have to say. Do not try to overawe the jury with your importance. Rather, let the jury be impressed by the quality of your testimony and the manner in which it is delivered. Do not indulge in pedantry. Do not speak down to the jury nor over their heads.

Consider what is almost insistence of medical witnesses in indulging in the use of such terms as hemiplegia or aneurism, which jurors do not understand and frequently judges do not understand, and how much further the doctor would ingratiate himself with court and jury if, when he feels that he must use these

terms, he were to promptly translate them into understandable English so that a jury would know that he was speaking either of paralysis of one side of the body or a tumor formed by an artery.

I close this discussion by repeating the words uttered in this room in 1928 by the then Chief Judge of the New York Court of Appeals, now Associate Justice Cardozo of the United States Supreme Court.

Some appropriate committee there should be in the bar association on the one hand and this Academy on the other, if none exists already, whereby the resources of the two professions can be pooled in matters such as this, where society has so much to gain from cooperative endeavor.

DOCTORS ONLY MAY "ELECTROCUTE" HAIR

The removal of superfluous hair by electrolysis treatments in beauty parlors by any one other than licensed physicians was forbidden on Dec 18 in a decision by the Bronx Court of Special Sessions.

As a result, the State Board of Medical Examiners and the office of John J. Bennett, Jr., State Attorney General, are to join in a campaign to stop the electrolysis treatments in hundreds of beauty parlors in New York City.

The decision was against Mary Lehrman of 2,800 Bronx Park East, a beauty parlor operator, who was arrested May 20, 1935, on the complaint of investigators operating under the direction of Dr. Harold Rypins, secretary of the State Board of Medical Examiners. She was accused of practicing medicine without a license. She was tried Oct 30. The court's decision was divided, Justices John V. Flood and Alfred J. Hoffman finding her guilty and Justice Lawrence T. Gressner dissenting. Sentence is to be imposed Jan. 22.

Sol Ullman, Assistant Attorney General, who conducted the prosecution, said the conviction was the first of its kind. Commenting on the electrolysis treatments in

beauty parlors, he characterized superfluous hair conditions as the result of a disease known as "hypertrichosis, which also constitutes a deformity."

"Electrolysis operators so treating a disease, deformity and physical condition, have sprung up like mushrooms overnight," Mr. Ullman said. "Without being required to have any proper educational qualifications, they are admitted to the so-called schools of electrolysis over which the Regents of the State have no jurisdiction or supervision. These schools give their students a brief course of instruction."

"Complaints have been made as to the operations of these electrolysis operators on the ground they are engaged in the practice of medicine and have treated the public for superfluous hair conditions, with the consequence that in some cases the appearance of those treated has been permanently marred and facial disfigurement for life has resulted."

Mr. Ullman said the special investigator went to the defendant's establishment and received two electrolysis treatments on the upper lip for the removal of superfluous hair. A charge of \$3 an hour was made.

PAN AMERICAN MEDICAL ASSOCIATION

The Pan American Medical Association announces that Temple University, at their Founders' Day exercises on February 15, will confer the honorary degree of Doctor

of Science on Dr. Charles Gordon Heyd, President of the American Medical Association and Dr. José Arcé, of Buenos Aires, in recognition of medical contributions.

EDITORIALS

Are They Satisfied?

Friends of compulsory health insurance in this country usually attempt to allay the doubts of American physicians concerning its alleged benefits by citing the general satisfaction of British panel practitioners with the system. That such satisfaction is neither real nor general, is suggested by recent letters in the correspondence department of the *British Medical Journal*, reproduced in part in the *J.A.M.A.* Complaints are directed against the low level of both medical service and medical payment as contrasted to the high costs of the system.

English panel practice is supposed to represent compulsory health insurance at its best because of the participation of the British Medical Association in the planning and administration of the system. If so, the best is still apparently far from good. Dr F S Taylor-Thomas calls attention to the mechanization of practice resulting from the popular demand for medication and the lack of time for anything else. "Juvenis" confirms this with the statement that he is "convinced the majority of patients do not get full enough investigation." Other correspondents frankly state that "to pretend that panel and well-to-do private patients can be treated identically is to be an ostrich."

Critics of obligatory prepayment are generally agreed that a patient should pay something at the time of receiving service in order to preserve his respect for independence and prevent unwarranted demands on the physician. Thus one writer, "My surgery hours are cluttered up with people who certainly would not come so often or drink so much medicine if they had to pay even one penny a visit." And another, "If * * * people * * * had only to pay 3d to see the doctor it would cut down England's drug bill by half." Throughout the same theme—of hypochondria and excessive medication directly attributable to the destruction of individual responsibility and integrity by compulsory sickness insurance.

Other recurrent criticisms emphasize the lack of opportunity for careful diagnosis and individual research. "Juvenis," already quoted above, complains that he "cannot do otherwise than rush them through" and remembers "with dissatisfaction" resultant grave diagnostic errors. As Dr Taylor-Thomas observes, "* * * insurance committees do not encourage academic excursions by general practitioners."

It must not be assumed from the foregoing that the panel system has no de-

fenders in the English profession. The *JAMA* quotes a former secretary of the British Medical Association and a chairman of an insurance committee, both of whom praise the quality of the service rendered. On the whole, however, the views expressed by independent observers are highly critical and go far to demolish the legend of medical satisfaction that American advocates of compulsory health insurance have tried so hard to build up.

Greater Maternal Safety

Recent amendments to the State Sanitary Code providing for the licensing of all maternity hospitals and homes, no matter how small, will receive the general approval of the medical profession. The high puerperal morbidity and mortality rates in this country demand the most stringent precautions during pregnancy and parturition. Absence of governmental supervision and control conduce to dangerous laxity in institutions headed by untrained or irresponsible persons. The need to secure a license—and to adhere to certain standards in order to retain it—places a check upon carelessness, avarice, and ignorance.

The regulations imposed are simple and sensible. Only a licensed physician, nurse or midwife may obtain a license to conduct a maternity home. The number of patients must be limited according to available space and equipment, minimum nursing care must be provided.

In their provisions for delivery the amendments endorse the rules observed by all reliable obstetrical institutions. Delivery rooms are isolated from bed and general operating rooms, and the maternity service as a whole is housed separately from other departments. The requirements for sanitation, asepsis, and fire protection furnish the minimum protection that prospective mothers have a right to expect for themselves and their offspring.

One of the important reforms which the new amendments will effect encompasses the question of records. In many of the small unincorporated maternity homes in particular, accurate records are virtually unknown. This not only deprives the state of valuable statistical data but encourages negligent and even illegal practices.

The revised Sanitary Code is not to be interpreted, as some rural practitioners and patients may have feared, as discouraging or putting beyond the pale of the law the familial assistance on which many prospective mothers rely in remote sections. The acceptance of a relative by blood or marriage into one's home for purposes of maternity care does not constitute operation of a maternity hospital. Without imposing any hardship on honest institutions, the new amendments may be expected to drive inferior mushroom institutions out of a field in which they are a grave menace to infant and maternal health.

"Hospital News"—Our New Section

We have always felt that our journal should be as broad in scope as is necessary to serve the profession in all its fields of interest. To this end, there is initiated in this issue a section devoted to "Hospital News." The relationship which exists between the individual doctor and the hospital he serves is more or less that of a "family affair." The broadest aspect of the situation, namely, the attitude of the organized profession and that of the hospital associations toward each other will, it is hoped, be better served by the addition of this new section.

Many problems of this relationship remain unsolved, and this is in no small extent due to the failure to understand each other's problems. The hospital has become indispensable in the modern practice of medicine and the changes wrought as a result of this require an elucidation

and revaluation of the physician's status in this relatively new phase of medical practice. As "Hospital News" grows, it will endeavor to make itself a forum for an interchange of ideas between hospitals and the profession so that a clearer comprehension of their mutual views and a cordial relationship may be attained and sustained.

We Become Active

With all the activity on behalf of compulsory health insurance and socialized medicine we are well acquainted. Until recently organized medicine has contented itself with keeping its members informed of the existence of an insidious form of propaganda which was being "dished out" to the public. The propaganda stage, however, has passed, and the advocates of health insurance are about to attempt to force its enactment into law, even though the public has as yet not expressed itself on this question. The overwhelming majority of the last election is being interpreted by the propagandists as a blanket endorsement of all and every form of so-called social security.

But it is the profession—the doctors who treat the sick and who have thus far done a good job of it in this country—who best knows the manner in which medical care can be given to the public. Therefore we are going before the people with our side of this question. Our most fitted spokesmen will present our views. Commencing with our President, Dr. Floyd S. Winslow, the *JOURNAL* publishes his remarks (page 192) as well as the fine presentations of Dr. Charles Gordon Heyd and Mr. Dwight Anderson. These addresses should be studied by all of us and also brought to the attention of our patients, and to our representatives in Washington and at Albany, so that these may not be stampeded into legislation which will be gravely detrimental to the well-being and the health of our people.

CURRENT COMMENT

NAPOLEON ONCE WISELY REMARKED, "America is a fortunate country. She grows by the follies of our European nations."

A "FOLLY" CURRENT IN FRANCE NOW IS its social insurance legislation. We quote from the communication of the Paris correspondent to the *J.A.M.A.* published in its issue of January 2, 1937:

"*** The application of the social insurance law has already affected the practice of medicine seriously and imposed a heavy burden, which the profession has accepted in a most loyal manner. Confronted with the proposed modification of the law, the profession feels itself entitled to claim an application of the law which will permit a physician at least to earn a living, hence the authorities are requested to consider the present plight of the profession in France before raising the limit of obligatory insurance. No one can ignore the loss of time, the vexatious examinations, the abusive investigations to which a practitioner is subjected in connection with the medical control demanded by certain caisses or bureaus which pay the claims for illness of the insured. These disagreeable encounters between the medical inspectors of the caisses and the practitioners, often taking place in the presence of the patients and tending to cause them to lose confidence in their medical attendant, should in the future be avoided ***"

"BY KEEPING THEMSELVES BUSY with accident prevention, public health folk will stay out of the mischief of interference with private practice *** With its personnel and administrative pattern the public health service is in an excellent position to correct the physical hazards and personal habits that do so much to increase the accidental death and disability roster in this country ***"—William Alan Richardson made the above suggestion in the December issue of *Medical Economics*.

"WE HAVE THE QUACK social reformers who would manufacture billions of paper money and distribute it to everybody, starting with the most lazy and most shiftless of the population. We have the political demagogues who are proposing to shackle us with laws that purport to relieve people from all care about their own future, and to guarantee conditions of comfort and se-

curity, regardless of tax burden laid upon the thrifty and industrious

"Our real task in this country is to keep open the doors of opportunity, and to make new opportunities if older ones become obsolete. We can make the schools fit the conditions of life. The educators and teachers are increasingly alive to the inspiring rather than the humdrum aspects of pedagogy. They are trying to train our future workers to be strong and capable, to be community-minded, and to be patriotic in the best sense. We can go much farther than we have gone heretofore in extending those social services that improve the health of growing children. We can supply the underlying conditions that encourage thrift and saving, and thus limit the percentage of those who will have to be aided or pensioned at the public cost. We can maintain our free, self-respecting American society, without failing to care for those who, through the vicissitudes of life, are unable to care for themselves"—Albert Shaw wrote the above, among other things, in his column "The Progress of the World" in the *Review of Reviews* for January 1937

"THEY WERE ALWAYS NUMEROUS, but now their name is legion. All over the world thousands upon thousands of men and women pass their whole lives denouncing, instructing, commanding, cajoling, imploring their fellows"—Aldous Huxley speaks thusly of propagandists in a current issue of *Harper's*

"THE MESSAGE OF ORGANIZED MEDICINE should primarily be of such a character as to make health a topic of lively and enlightened interest to everyone. This is not to be accomplished by scaring people. What is needed is an expert portrayal, in appropriately dramatic manner, of the genuine truth about the marvelous accomplishments

of medicine, both in its science and in its art. Definite facts must be given to paint a truly attractive picture of the quality of medical service which these advances enable physicians to render to all who seek their counsel. All the various components of medical care—the work of the physician himself, hospitalization, nursing, laboratory work, radiology, etc.—all these should be properly dealt with in order that the ignorance and misinformation concerning them, which unfortunately exists even among the more intelligent classes, may be completely dissipated.

"The message of organized medicine must aim to improve the relationship between physician and patient if it is to be successful in weaning the public away from self-dosing and patent medicines *** The message of organized medicine must further tell the American people, in clear understandable language, why the American system of medicine must be preserved if the quality of service is to be kept up to its high standard of today. Yes, and the real truth about socialized medicine must be driven home to the public at large, so that this notorious poor-house system of medicine, which so dismally falls short of its vaunted objective, cannot gain a firm foothold in our land. State medicine must not come with its standardized impersonal production methods to sever the personal, confidential, and even sacred relationship which must exist between physician and patient in order to achieve the optimum results in treatment. Socialized medicine must not come to retard the progress of our scientific advancement in America. Medicine in our country must remain unshackled and free from the log-rolling and foot-balling and pork-barrel taint of grasping political systems ***"—"Will Organized Medicine Speak to the People?" is the title of an article written by Elmer H. Robst, published originally in the *Roche Review* for December 1936, from which we have quoted in part

A P L I

The Annual Meeting of the Associated Physicians of Long Island will be held at the St. John's Hospital, Brooklyn, January 30

From 10 30 a.m. to 1 00 p.m. operative clinics will be discussed by the surgical, obstetrical and gynecological staffs of the hospital. Members will be guests of the

hospital for luncheon at 1 30. At 2 30 a pathological conference will be held in the hospital museum. The scientific session will begin at 3 00. The dinner will be held in the Hotel Granada at 6 30. The speaker will be Mr. Howard Scott, Director-in-Chief, Technocracy, Inc., on "International Health in a Changing World"

Researches in Blood Flow

35 East 84th Street
New York City

1035 North Calvert Street
Baltimore

o the Editor

After reading the paper by Thomas P. Sprunt in the issue of November 15, 1936, I came to the conclusion that doing research is just a waste of time. I marvel at the manner in which these modern writers and workers overlook and overcome scientific attempts that were published before their immediate period of activity.

I thought I had done some basic work on the volume and speed of the blood flow and blood pressure, and now I find that not a single one of my researches as published in *Pfluger's Archiv*, the *Quarterly Journal of Physiology*, and the *Journal of Physiology*, has been regarded sufficiently valuable to be cited. I notice, however, that many of my figures, etc., have been incorporated in this article without proper process of transfer.

Very truly yours,

R. BURTON-OPITZ

December 3, 1936

To the Editor

Many thanks for your letter of Dec 16th with the copy of Dr. Burton-Opitz' letter.

Every student of the circulation is familiar with Dr. Burton-Opitz' fundamental work in this field of physiology. It is a part of our basic knowledge.

The purpose of my brief paper was to "review certain recent additions" to our knowledge and there was no opportunity to present the development of the subject.

Dr. Burton-Opitz' figures on blood flow in different organs are copied in most textbooks of physiology. The author deeply regrets that they were not credited to him in this paper although, of course, anyone using the reference given would have found his name among the original sources.

Very truly yours,

THOMAS P. SPRUNT

Dec 22, 1936

HOBBIES AND MENTAL HEALTH

The possession of a hobby has come to be regarded as an almost essential ingredient of a healthy and well-balanced personality. When the monotonous routine of the daily grind irritates beyond endurance, and whenever one's family and friends are hopelessly misunderstanding, if a person has cultivated a keen interest in some activity, or in something aside from the occupation which gives him his daily bread, he will generally find that the pleasure derived from his hobby will compensate sufficiently for his financial and social frustrations, so that a complete breakdown is avoided, says David Ruslander, M.D., of the Buffalo State Hospital, in

Mental Hygiene News. The story is told of a young man who, while contemplating suicide, happened to think that his pet pigeons might be neglected, and we have his word for it that it was that thought that gave him the determination and courage to face his difficulties.

Where a mental disease has already developed, psychiatrists often utilize a hobby formerly possessed by the patient as a fulcrum to pry the patient away from his abnormal adjustment and with the indispensable help of the occupational therapist, the patient is won back to mental health.

The 441st regular meeting of The Society of Medical Jurisprudence was held at The New York Academy of Medicine, December 14.

An address on "Case Reports from the

New York City Medical Examiner's Office" (illustrated with lantern slides) was given by Robert C. Fisher, M.D., Assistant Medical Examiner, New York City, followed by discussion by members.

Addresses by the President of the Medical Society of the State of New York

Following his induction into office as President of the Medical Society of the State of New York, Dr Floyd S Winslow has delivered addresses before District Branches of the State Society, before several County Societies in the State and has appeared before the public as spokesman for the profession of the State both over the radio and in the press. Through the Committee on Medical Trends of the State Society, a number of these speeches have first appeared in publications other than the JOURNAL because that committee considered them of such vital import at the present time as to deserve a wider distribution to both the public and the medical profession than the JOURNAL could furnish. Certain of them have been collected for reproduction here in order that the entire membership of the Medical Society of the State of New York shall be able to enjoy their perusal and keep them for reference. We are certain that they represent accurately the thoughts and policies of organized medicine in New York State and it is our opinion that Dr Winslow's sayings merit a permanent place in the record of medicine's effort to supply the best possible medical service to the Community—EDITOR

WE DO NOT WANT SECURITY

The Doctor's Obligation

FLOYD S WINSLOW, M D,

President, Medical Society of the State of New York

It is the supreme obligation of the medical profession to provide the public with medical care of the highest possible quality, and to protect them from the results of inferior service.

Sometimes we get so close to the subject matter of our work, that we fail to see it in the true perspective. It is my purpose here to discuss the most important activities of the Medical Society of the State of New York, and show just how each of them fits into this definition. Each one, as we shall see, either promotes the health and well-being of the people by making our membership better qualified to serve their patients, or operates to the same end by opposing and resisting those forces which either would interfere with our competency, or substitute incompetency.

First in order, if not in importance, are the courses in graduate education, which are given as county medical society programs under the sponsorship of the society's committee on public health and medical education. This committee has assumed important responsibilities in the field of public

health, and with suitable sub-committees, is concerned with such matters as pneumonia control, cancer, syphilis, maternal welfare, child hygiene, and nursing education.

The point is made merely when it is stated, these activities increase our capacities. But not only do they do this. Through the cooperation which results from contacts with official and voluntary health agencies, these activities also increase the popular acceptance of our capacities.

It is not my intent here to labor the point, or to bore you with details of the work of the various committees. But in passing I should mention the committee on scientific work, in whose charge is the important task of arranging the scientific programs at the meeting of the state society, the public relations committee, whose chairman directs the activities of his group in such matters as the examination of school children and the problem of the care of the deaf and hard of hearing children of the state. It is clear how these matters fulfill our supreme obligation to provide the public with medical care of the highest possible

Delivered before the Sixth District Branch of the Medical Society of the State of New York, Ithaca, September 17, 1936

ality Two other standing committees remain to be examined These are the legislative and economics committees The former is active at all times to "spot" provisions in bills proposed to the legislature which may be damaging to the public because of the effect they have upon medical care Often these provisions are thoughtlessly inserted by their proponents who are ignorant of the effect of some minor provision in a law Inasmuch as there are 6,000 bills introduced in every session of the legislature, it is easy to see the need, in protecting the public against inferior medical care, for active effectual work on the part of this committee The economics committee easily fits into the latter section of our original definition, "to protect the public from the results of inferior service" We all know how ably this committee has presented the facts concerning compulsory health insurance, how in every foreign country where it has been tried, medical care has suffered deterioration. We need to be told these things over and over again The advocates of socialized medicine lure the profession with the siren song of bureaucratic jobs, assured income—security—false security We do not want to be secure. We want to remain insecure. We want to continue to be required to give our very best to every patient, or lose out in the gentlemanly competition which exists within our ranks This is an incentive that operates to our insecurity, but to the security of the patient. We prefer the discipline of private practice which keeps us on our toes, to an assured income under bureaucratic control where our highest ambition is more likely to be to keep ourselves solid with the politicians who have taken over the job of running our profession

I repeat, security for the doctor means insecurity for the patient

The state-wide attack on pneumonia which was instituted by the Medical Society of the State of New York last year, will be continued this season In cooperation with the State Health Department, and various other agencies such as the Commonwealth Fund, Rockefeller Institute for Medical Research, and the Metropolitan Life Insurance Company, plans have been crystallized for rendering serum available throughout the State, for the education of the medical profession and for the popular instruction of

the public It is hoped ultimately to reduce the mortality from this disease in New York State by three thousand lives per year In connection with this campaign, the committee on trends of the society has cooperated with all these agencies in the preparation of popular educational material, consisting of facts about pneumonia for editorial writers, radio talks, feature articles, and specific plans addressed to informing the public of these three facts.

First Medical handling of these cases is just as much an emergency as acute appendicitis,

Second Early recognition is of vital importance,

Third Proper nursing care is equally important.

This popular publicity has been prepared by the Public Relations Bureau of the Society, and will soon be ready for distribution throughout the State

During the winter it is likely that each county medical society will be requested to designate a member to speak on the radio or at public meetings on this subject May I urge you to accept this responsibility as a way still further to place the organized medical profession in the position of leadership in public health activities, many of which in the past have seemed to appear so importantly in the public eye on behalf of non-medical groups as to imply that the medical profession is indifferent to these aspects of its high responsibility

This brief recapitulation of the activities of the society, barren as it is of details, could be expanded extensively by inclusion of the mass of data which is required to be digested to pursue these policies, of the hundreds of stated meetings and personal interviews which are part of the big job which organized medicine has assumed in this State

And it cannot be too emphatically put that it is incumbent upon us, by the pursuit of such measures as these, to prevent those whose occupation is to *talk* about medical care, from inaugurating visionary proposals tending to prevent us, whose occupation is to *provide* medical care from keeping faith with our patients and with the public. We have been accused of thinking only of our bank accounts when we oppose compulsory health insurance. When

did we ever think in terms only of our bank accounts? Where is there another profession which is so impersonal in its primary objects, working so surely, and so effectually, fighting every kind of disease, driving out of existence, if it were possible to do so, the very source of our income?

William MacDougall once said that civilization began when man discovered that he could satisfy his egoistic and his altruistic impulses in a single act. Through the centuries the medical profession has been disciplining itself as a hard master would discipline a student of whom he had the highest hopes, through the centuries we have been perfecting ourselves to fulfill the great obligation to society which is our privilege. Today, the American public is the recipient of the best medical care in the world, and I need not bother you with

the statistical evidence that with few exceptions, our death rates are below all those countries where the doctor's activities have been painfully made the object of the state's beneficence.

We want to remain free to advance ourselves in the way we do now, by service rendered to the patient, or by service rendered to the public as a whole. If Mac Dougall is right, and there are people who think that a man may have been a professor in a college and still sometimes be right—collectivism as an incentive to replace in individualism—would be a step backward. Our obligation would then be shifted from our shoulders and become the obligation of society as a whole. This is too great a diffusion of responsibility. Those who know the least, but who talk the most, would control

PARTNERS IN PUBLIC HEALTH

FLOYD S WINSLOW, M D, Rochester

President, Medical Society of the State of New York

Anybody can tell us what a public health person should know, if somebody will first tell us what that person is to do.

Public Health workers and private practitioners alike engage in an occupation whose purpose is the improvement of people's health. The health officer's work is extensive, that of the doctor is intensive, that of the public health nurse may be either or both. The health officer thinks in terms of cases of pneumonia, the doctor thinks in terms of persons with pneumonia. The health officer is more or less abstract and communal in his attitude, the doctor is essentially concrete and individual, the nurse often serves as a link between the two and an interpreter of their aims to actual or potential patients.

None can get along without the others. We should be more than just acquaintances, we should be friends. We should understand each other more fully than we do and we should cooperate to better purpose than we have sometimes done. It is easy to be critical. I admit at the start that the average doctor might very well know more about community health problems, the value

of vital statistics, the importance of certain sanitary procedures. On the other hand, the health officer might well understand more about conditions as the doctor encounters them in the sick room, the personality problems involved in almost every one of his relationships, the difficulties which stand in the way of his obtaining the cooperation of the patient in some particulars without seriously disturbing the whole confidential relationship. To a health officer, statistics on a chart may be too easily interpreted as failures of private physicians to achieve ends which bulk black on the roll of the community's total, but to the individual doctors, these imperfect results may mean, in each case, the best that could be accomplished under the given conditions. Angels perhaps could have done no more—health officers, even if endowed with plenary powers of compulsion, might have done much less.

I believe I could write on the imperfections of the medical profession until the celebrated Saratoga Springs ran dry. The trouble with us is that we are so busy with our individual cases of people who are sick that we have no time left to devote to ag-

gregates of sick people, and we fail to sympathize as fully and instinctively with communal purposes as no doubt we should. Some have been kind enough to point this out to us on a number of occasions, it must be admitted that we are improving. On the other hand, there are those of us who think that some public health efforts are operating to increase the number of instances in which persons who should go to a private practitioner are allowed to feel secure in the advice of persons of inadequate ability and experience.

That popular health instruction in the mass and individually is a part of the function of health departments, as well as the obligation of voluntary health agencies, is clear from the examination of their activities. The school nurse and the school physician, for example, are strategically placed to protect the school body in many particulars which would never pass under the observation of the family doctor. They can do things which he cannot do in this respect, therefore they should do them. But are they ready to assume the responsibility for diagnosis or treatment, and do they realize fully enough that they may be innocently diagnosing or treating when they think they are doing educational work?

What matters is not the purpose but the effect of that which is done. The difficulty of the public health worker's position, particularly that of the nurse, is apparent. She, like the doctor, must obtain and retain the confidence of the people she serves. It is difficult to say, "You should see your doctor," when an apparently trivial question is asked. It is easy to respond to a request to be more specific. The extent to which the nurse may be substituted for the doctor, quite unintentionally on her part, is not to be overlooked as one of the problems inherent in the extension of her activities. Should she express opinions on conditions of individual persons even when coupled with a warning to "see your doctor?" The temptation to do so is great and the more confidence in herself which she establishes, the more frequent and insistent will be the temptation. Yet she will be the first to admit that she is not ready to accept the full responsibilities of such a relationship.

If we agree that vital statistics can only tell us where to apply therapeutics and not how, that the healing process cannot be performed by means of surveys, that a

person with public health training is not equipped to diagnose or prescribe, then we should agree that in the last analysis, the health of the community will depend to a great extent on what goes on in the doctor's office and in the sick room. No other situation in the picture can be more important. Yet no other situation in the picture receives less popular emphasis outside the strictly medical forum of the medical school, the clinic, and the technical journal.

I do not decry health instruction. It is of value especially when it results in action on the part of those to whom it is directed, which is not always the case. Often, I fear, it either unduly frightens or unduly allays disquietude. Prevention is important, but the most effectual prevention is not a story in a newspaper, but the story which the doctor tells the patient after he has examined him. The official and voluntary agencies do well to create a demand for preventive medicine. It is then undoubtedly the province of the doctor to administer these measures.

The delineation of functions in a composite administrative picture is never an easy one—since human beings are not absolutes—which may be blue-printed with certainty. The head of a great establishment employing thousands of persons once examined a chart of his organization on which he and his executives had labored, and said with a smile, "This all looks very fine, but how long will we be able to keep these people inside their little rectangles?" He might also have asked, "How long would I wish to do so, if my organization is to continue growing?"

Every group possesses something like a biological will to live, and tends to increase its powers, as we know is true of all individual life on this planet. Every group has the virtue and the vice, the insight and the blindness, of its peculiar species. Community deathrates are meaningless to the physician who wakes up in the middle of the night, asking himself if there could be anything additional that he might have done for the cases which are most upon his mind. These sick people are his responsibility. His days and nights are occupied with the seriousness of this responsibility. When he has a moment to spare he wishes to study, to keep up with the march of medicine. He has no time to devote to statistics of

thousands of persons unless he is specially interested for some reason other than clinical

Persons in the mass are not his responsibility. They are the responsibility of public health authorities to the extent, and in the degree, that it is possible to do something for thousands of persons en masse. But you cannot diagnose thousands of persons as thousands, but only as the sum of individual diagnoses, you cannot treat the diseases of thousands of persons except as the sum of individual treatments, therefore the public health function ceases where diagnosis and treatment begin. I would go a little farther and say it ceases when education or instruction is in fact construed by the recipient as diagnosis or treatment.

The public health groups and voluntary health organizations have done an excellent job of teaching the people certain scientific facts which have not only sent them to the private practitioner for help when they needed it, but have sent them better prepared to be good patients. Taboos are being removed which kept people from seeking medical care, especially in tubercu-

losis and syphilis. In many other ways the medical profession should be thankful for the work of these groups which are able to tell the public things which the doctor cannot tell them without loss in public esteem, and therefore in healing ability. However it is possible for one to learn and teach the value of an x-ray in suspected tuberculosis without really knowing anything about x-rays. The word "shadows" may be used by a person who does not know whether shadows show black or white on a negative. This is merely to say that it is not necessary for the salesman of preventive medicine to know how to conduct a physical examination, just as a man can sell automobiles who could not make one. By the same token, care should be exercised that these official and voluntary groups in easy access to the public mind do not become substituted, through identification with the subject, for the services which only a trained and experienced physician is able to provide. Wise is the man, be he the doctor or one of his co-workers, who, with Plato, can say, "What I do not know, I do not think I know."

CAN THE PUBLIC BE TRUSTED?

FLOYD S WINSLOW, M.D., Rochester

President, Medical Society of the State of New York

In many quarters it is felt that the time has come for organized medicine to address itself to the public in a way that it has never done before. As a body, we have always been ready to respond to any reasonable requests for information or advice on medical or related subjects. As individuals, we have never been remiss in assisting, usually without compensation, public agencies which needed our help. This has often been done when the direct effect was contrary to our personal financial interests. But what is meant is something further than this.

It seems now, that in a changing order, more is required of us. Upon every hand we see the evidences of overt and systemized efforts at persuasion, direct and indirect in presentation, but studied and planned.

Of course it will never be necessary nor

compatible with the position we occupy in society, for doctors as a group to descend to the devices of the professional propagandist. But the question has been raised, and we should all give it considerable thought, whether we may not make ourselves more vocal than we have been, which means to change our attitude a little and take the public more into our confidence.

Laymen are assuming the right to discuss and decide many questions which we have thought were exclusively for our determination. The idea was expressed forcibly in a recent weekly publication by a writer who used these words: "As an occasional purchaser of medical services I am as much entitled to my ideas of what is represented by medical care as is the doctor—so is any patient for that matter."

Now we all know the dangers which lie in self-diagnosis and treatment—dangers to the patient. We all know the pitfalls which the practitioner is sure to fall into if he attempts complete explanations to the patient of everything concerned with individual cases. The patient has neither the knowledge nor the experience to serve as a background to help him understand what we may tell him, and misinterpretation of our statements is more frequent than is adequate appreciation.

We can easily tell too much for the patient's own interest. This, of course, is an individual problem, and depends on the intelligence and the emotional character of the patient himself. But may I call attention to the fact that the same rule of reticence may not apply to medical subjects which are economic or sociological, and, if so, that our attitude toward the public on them should be changed?

The writer I have mentioned is partly right, though his statement is too general. If he were to limit the realm in which he is entitled to an opinion to matters such as sickness insurance, then we would agree with him that he is entitled to an opinion, as a purchaser of medical care, though it might be a very wrong opinion, and one exceedingly damaging to himself and others, if it should prevail. My point is that there have arisen a number of questions related to the work of our profession, which are not essentially scientific or therapeutic, and on which a lay person with a trained mind may be equipped to form a sound opinion.

At any rate, we face a situation where such questions as these have definitely been withdrawn from the medical forum and placed in the forum of public opinion. It is not going to be enough for us to dismiss opposing ideas on these things with such oracular statements as "The medical profession alone is a competent judge of how medical care should be distributed."

I think I hear somebody whispering that it is dangerous for us to relax our attitude and perhaps later find ourselves forced to accept the judgment of the arbiter before whom we have stated our case. We will agree that on questions inherently medical our prerogative to decline discussion and to confine ourselves to more or less arbitrary authoritarianism should be maintained. On these other questions such as sickness insurance, vivisection, and the licensing of cult

practitioners, let us examine carefully whether or not, in general, the public may not be trusted to form a sound opinion. For we cannot with good grace admit them worthy even to be persuaded, unless we have some degree of confidence in their ability to form a wise judgment, after they have had the advantage of an adequate presentation of the material intendments of the subject.

I have two examples to cite to you which seem to bear directly on this point, and which lead me to believe that in general and after the public has been fully and fairly informed on both sides of any controversy, the resulting majority view is of a far sounder character than many of us think. Yet again I must ask that we distinguish clearly between what I am calling the medical and the quasi-medical realms.

During the course of the recent nationwide high school debate on state medicine many medical men were disturbed by the insidious character of the propaganda to be foreseen as one of the results—perhaps the intended result. We were quite suspicious of the whole undertaking. You probably know that five thousand debating coaches in all parts of the country engaged in training debaters for these high school contests.

Plenty of material on both sides of the question was made available to the debaters, principally through the excellent work done by Mr J. Weston Walch of the Debater's Information Bureau, of Portland, Maine. Both sides were well presented in this material. And we have Mr Walch's statement in a recent issue of *Medical Economics* that the side against state medicine is much the easiest side on which to build a strong case, in the opinion of many debating coaches. The instructors, he states, in their personal opinion, lean heavily toward the present private system. Says Mr Walch: "Those with whom I have talked and corresponded have been most concerned, first, over the political and bureaucratic interference that would follow socialization, and second, over the almost unbearable cost which would have to be met by some form of increased taxation."

It looks very much in this instance as if an informed public could be trusted with the solution of such a question as this. If the choice of this debate topic was a devious propaganda device of the agents of medical socialization, the bird they loosened came right back home to roost.

thousands of persons unless he is specially interested for some reason other than clinical

Persons in the mass are not his responsibility. They are the responsibility of public health authorities to the extent, and in the degree, that it is possible to do something for thousands of persons en masse. But you cannot diagnose thousands of persons as thousands, but only as the sum of individual diagnoses, you cannot treat the diseases of thousands of persons except as the sum of individual treatments, therefore the public health function ceases where diagnosis and treatment begin. I would go a little farther and say it ceases when education or instruction is in fact construed by the recipient as diagnosis or treatment.

The public health groups and voluntary health organizations have done an excellent job of teaching the people certain scientific facts which have not only sent them to the private practitioner for help when they needed it, but have sent them better prepared to be good patients. Taboos are being removed which kept people from seeking medical care, especially in tubercu-

losis and syphilis. CAN THE PUBLIC BE TRUSTED?

FLOYD S WINSLOW, M.D., Rochester

President, Medical Society of the State of New York

In many quarters it is felt that the time has come for organized medicine to address itself to the public in a way that it has never done before. As a body, we have always been ready to respond to any reasonable requests for information or advice on medical or related subjects. As individuals, we have never been remiss in assisting, usually without compensation, public agencies which needed our help. This has often been done when the direct effect was contrary to our personal financial interests. But what is meant is something further than this.

It seems now, that in a changing order, more is required of us. Upon every hand we see the evidences of overt and systemized efforts at persuasion, direct and indirect in presentation, but studied and planned.

Of course it will never be necessary nor

compatible with the position we occupy in society, for doctors as a group to descend to the devices of the professional propagandist. But the question has been raised, and we should all give it considerable thought, whether we may not make ourselves more vocal than we have been, which means to change our attitude a little and take the public more into our confidence.

Laymen are assuming the right to discuss and decide many questions which we have thought were exclusively for our determination. The idea was expressed forcibly in a recent weekly publication by a writer who used these words: "As an occasional purchaser of medical services I am as much entitled to my ideas of what is represented by medical care as is the doctor—so is any patient for that matter."

So let's sit down together for a moment and talk things over—the doctor and the public. I welcome this opportunity to do so today as guest editor of the *Rochester Journal*

What actually goes on at medical meetings? Doctors get together for a number of different purposes, but principally to learn from each other better methods of practice—how to be more effectual in healing the sick. This is the scientific aspect of our meetings. There is another aspect. It is the social aspect. Most people are unaware that the Medical Society of the State of New York participates in one way or another, either by approval and advice, or by active, energetic action, in such public health saving programs as pneumonia control, child hygiene, tuberculosis, cancer, maternal welfare, and nursing education.

At present we are preparing for an effort during the winter months to cut down the ravages of pneumonia. These are the things that we are undertaking to teach the public about pneumonia.

Medical handling of these cases is just

as much an emergency as acute appendicitis.

Early recognition is of vital importance.

Proper nursing care is equally important.

If these activities and many others are not known to the public, whose fault is it?

Frankly, it is our own. We have been indifferent to the public. We have felt it was enough for us to do these things, and let others talk about them.

But "times change, and with them customs." The medical profession is becoming vocal. Whereas it was formerly considered undignified for the doctor to address himself to the "lay" public, we now feel that this is a most valuable contribution for us to make to the public welfare.

So the public may look for us in the future to explain more than we have in the past about what we are doing and planning. We may not always be as talented at telling as we might wish, but our friends, the newspapermen, will help us, I am sure. This will make us better doctors, and I suspect it will make the public better patients, too.

WHY DO WE HAVE MEDICAL ETHICS?

FLOYD S WINSLOW, M D ,

President, Medical Society of the State of New York

There is probably more popular misunderstanding on the subject of medical ethics than on any other connected with the practice of medicine, and yet perhaps there is no subject which has more to do in a vitally controlling way with the service which the profession of medicine is able to render to the public. Why do we have medical ethics? What is this code of behavior to which the doctor is bound? Does it operate for his benefit, or for the benefit of the patient, or for the benefit of both?

Everybody has a code of ethics, though few go to the trouble of formulating it. Your code, whatever it may be, consists of the standards, or principles, which guide your conduct. Ethics has to do with what is right or wrong in the given circumstances. And everybody's code is revealed in what he does, not in what he says.

Now a code which will do for one occu-

pation or pursuit may not be practical for another. There is a story which illustrates the point. Two men were in partnership in the grocery business. One day one of them said to the other "Bill, what's all this I hear about ethics? What are ethics, anyway, do you know?"

"I'll tell you, Charley," Bill replied. "Here's an example. A man comes in to buy some goods while you are out of the store. He buys ten dollars' worth, and gives me a ten dollar bill. I take it over to the cash register, and when I start to put it in, I find there are two ten-dollar bills stuck together—the man has given me twenty dollars instead of ten. Now this brings up a question of ethics. The question is shall I tell YOU?"

That's one kind of ethics. We will all agree it is not the kind that should be encouraged, nor is it the kind on which a

The other example which has been called to my attention comprises certain results of surveys made by Dr George Gallup of the American Institute of Public Opinion, Princeton, N J. Dr Gallup takes issue with the statement that "the public is always wrong." He cites findings which lead him to prefer Lincoln's statement "Why should there not be a patient confidence in the ultimate justice of the people? Is there any better or equal hope in the world?"

Dr Gallup's organization conducts what amounts to a continuous poll of popular opinion throughout the country. This work is done on behalf of a number of subscribing newspapers. The institute has a staff of 150 trained investigators who supplement with interviews the results of thousands of ballots mailed out. Five controls are used, not only to secure proportionate returns on the basis of state populations, but also of residence on farms and in cities, income groups, and voting ages. The polls conducted by this institute has never varied more than two per cent when checked against popular elections.

I cannot here go into the results of a number of polls which have demonstrated to Dr Gallup that in general the people are to be trusted in decisions on public affairs. I shall content myself with quoting from one of his reports merely as to a single poll. Says Dr Gallup "About the middle of December we reported on one of the most interesting polls we have conducted. The question was 'What do you think is the most vital issue before the American public today?' Each voter had to write in his choice. The three issues that led the list

were 'Cure unemployment, stop government waste, stay neutral'."

Then Dr Gallup asks the question "Does that look as if the people lacked political brains?"

Now I am free to say that I think there are certain exceptions to the rule that the public may be trusted. But there are even more serious objections to assuming that they can not be trusted, and that only a small group of men superiorly endowed are worthy of trust. History relates as many political vices under monarchy as under democracy, and you can take your pick whether you like the sneer of the patrician better than the leer of the plebeian.

We are living for the present at least under a system that resembles democracy more than any other, and we cannot ask that it work perfectly at all times and under all conditions. We as physicians know better than to expect that of anything to be found in this mundane world. And I am free to say that I think the public as a whole is well able to decide questions on which it is possible for them to form an opinion at all. Except in times of mob hysteria, or crowd elation or depression, such as the last decade has witnessed, the public can be trusted more than we think. Provided, always they are fully informed. Provided in the instant matters under discussion, we take the initiative, go to the trouble to inform them, and talk to them in their own language, easily, colloquially, forgetting perhaps that we are doctors and remembering only that we are citizens.

I suspect that the public can be trusted if we trust them enough.

THE DOCTOR AND THE PUBLIC

FLOYD S WINSLOW, M D,

President, Medical Society of the State of New York

There should be no misunderstanding between the doctor and the public.

Yet it is unmistakably evident that people who trust their doctors with their very lives, are just a little reluctant to give full faith and credit to them when they act in groups.

There can never be misunderstanding between two persons who sit down together to talk over their differences all the way through. They will at least agree on just what they cannot agree upon, which is the first step in composing differences.

The Rochester Evening Journal and the Post Express inaugurated a policy of having as "Guest Editor For A Day" in successive issues a number of prominent citizens of Rochester, N Y. On the occasion when Dr Winslow accepted the invitation to be the guest editor (October 6, 1936) his contribution was the above editorial.

tion from the patient, sometimes by using the arts of the cross examiner. To some he must be gruff, with others mild, he must at all times be ready to recognize when self-diagnosis by the patient prevents him giving a true picture of his symptoms. On the one hand there are persons ready to think they have any disease which is in the current of the popular thought of the moment, and there are persons of whom it can almost be said they will not believe they have a disease until they have died of it. The doctor must recognize the type of personality with which he has to deal, and adapt himself to each type by a suitable method. But confidence is always the basis of the relationship when it is at its best, and by this I mean when the patient is getting the most he can, and the doctor is giving the most that he can.

Now confidence, as somebody once said, is a plant of slow growth. It cannot be forced in the hot-house of self-praise. There was a time, when it was quite common for every town to have one or two advertising doctors, whose claims to cure almost everything by "new" methods, were brought loudly to the attention of the public. The public has to thank for the elimination of this outright vicious quackery, the newspapers themselves, who profited most by it, and yet who came to see the damage which was done to the public when persons were allowed to solicit patients in this way. Invariably the physicians were incompetent. Otherwise, they would not have been driven to the point of obtaining patients by bragging. For some reason or other, these doctors had forfeited the good opinion of the people they knew so that patients ceased to come to them, and they took the next step—the only one left to them within the ranks of medicine—to advertise for patients and accept people who knew nothing about them except as they might believe part of their extravagant claims. Being unable to make good on their promises, they obtained no new patients through the recommendation of old ones, and had to continue to rely on the beguiling of strangers. Advertising by doctors, direct or indirect, is vicious from every standpoint. It encourages practitioners to make claims they cannot justify, it robs the relationship of that bond of confidence which can only be built on years of service in the community. It encourages emphasis on the arts and devices of the advertising and sell-

ing business to the disparagement of meritorious medical work which will ultimately become known through the recommendations of patients well served. So we have this rule, which I also quote from the "Principles of Ethics": "Solicitation of patients by physicians as individuals, or collectively in groups by whatsoever name these be called, or by institutions or organizations, or by personal communications, is unprofessional."

I need not go farther in discussion of the many other rules of professional behavior. While most people are not aware of them they may be observed in the conduct of physicians of any community. They all operate for the benefit of both the doctor and the patient, not, as many people think, for the benefit of the doctor alone. They are standards of conduct, which as Dr. Cabot said, have a practical end. The practical end is to enable the doctor to do his best for the patient. Most of them have to do with perfecting a confidential relationship which is essential to doing good work. The opposition of the profession to state medicine is based on this principle. State medicine would destroy this confidential relationship by interfering with the free choice of physicians. Whereas now the incentive of excellence is the motive power of the profession, under state medicine the incentive would not be to please the patient, but rather the officials in charge of the public machinery of medical administration.

There can be no rights without obligations. We who follow the healing art cannot assume its rights without certain obligations, as we have seen. Can the public, then, assume the right to call on us in distress without assuming the obligation to see that we are allowed to retain our high ideals of competence? Is it not the obligation of the public to see that as a group, we are sufficiently well compensated so that we can preserve our standards without the temptation to resort to the shyster methods of the cheap charlatan? If we are to be good doctors, you must be good patients. You must help us maintain the present high standards of private practice by joining with us in resisting any tendencies to lower the rules of conduct by which we are able to give you our very best. You call upon us when you are in need, and we come. If the time ever arrives when we are in need we shall call upon you to help us preserve these standards.

permanently successful business can be built. What is right and what is wrong? Is what is right for one man right for everyone else, and is what is wrong for one man, wrong for everyone else? Dr Richard Cabot, a physician of Boston says "Most of what used to be called goodness has rightly fallen into disrepute because it is inefficient. As I see it, ethical diagnosis, like physical diagnosis, has a practical end."

Dr Cabot believes that a code of ethics is composed of tacit agreements between people, so that each one knows what to expect of the other. The question doubtless has arisen in the minds of most thinking people, why shouldn't I do as I please? Why should I be bound by any rules or responsibilities to duty, or to custom, or to public opinion? And the answer simply is that other people won't let you keep on breaking the rules—you cannot permanently get by—you will be found out in time, and then others will cease giving you the things you expect from them because you have failed to give them what they expect of you.

In a word, there are always certain guiding principles of behavior among all groups and in all relationships of life. They differ and they change but they constitute working agreements that enable us to live together. So there are guiding principles between the doctor and his patient, principles the doctor must observe to be permanently and genuinely successful. I am intending to discuss some of them briefly. There are also principles of behavior the patient must observe, if he is to be a successful patient, and get all that he expects to get from the doctor. And I intend to discuss some of those principles, too.

Let me quote from what are known as the Principles of Medical Ethics of the American Medical Association "A profession has for its prime object the service it can render to humanity, reward or financial gain should be a subordinate consideration. The practice of medicine is a profession. In choosing this profession an individual assumes an obligation to conduct himself in accord with its ideals."

The rule which I have quoted is seen to be peculiarly effective when we find medical men freely giving to the world every discovery or improvement in technique which they may make. This situation is not matched in any other calling or pursuit. An engineer who invents a new process or device gets all the advantage of a patent,

a writer who creates a worthy novel or play gets all the advantage of a copyright, the doctor gets nothing. Only the quack has a secret "cure" which he claims is his own infallible method. The kind of man capable of making a contribution to the care of the sick is always the kind of man who at once makes his knowledge known to the medical profession and thus to the world, which has the advantage of it free of any royalty for use. The discoverer's reward is often greater than any monetary one could be—the satisfaction of having done a useful service, and perhaps also, great personal prestige. Now while financial gain is, I am glad to say, a subordinate consideration in the mind of the doctor, it still must be a consideration if he is to pay his bills, and continue to heal the sick. The patient expects from the doctor the best he can give, and the doctor expects from the patient the best he can give, too. And the best the patient can give is not only to pay his doctor when and as he can, but even more importantly, it is to be sure to hold nothing back, to tell him fully everything that can possibly affect his condition. Another thing that the doctor has a right to expect is that the patient shall follow the advice and directions which he receives.

I have time to discuss only a few of the principles of medical ethics. First is one which flows naturally from the previous one. If there is an obligation on the part of the patient to withhold no information from the doctor, then, there must be, and there is, a responsibility on the part of the doctor to preserve this confidence. Again quoting from the "Principles of Ethics" "The confidences concerning individual or domestic life entrusted by a patient to a physician and the defects of disposition or flaws of character observed in patients during medical attendance should be held as a trust and should never be revealed except when imperatively demanded by the laws of the state."

So here we have, in the code of ethics, the protection which is given the patient for a full and complete disclosure to his doctor. Unfortunately, there is no code for patients, to which all persons must subscribe before they enter a doctor's office, but if there were, one stipulation as a basic provision, to enable the patient to get what he needs, would be worded like this **TELL YOUR DOCTOR EVERYTHING**. The doctor must at times obtain his most important informa-

the first meeting of the American Medical Association was held in Baltimore in 1848.

It appears that the primary and social purpose of all of these various stages in medical evolution was based upon two distinct aspects of organization (1) to provide a high quality of medical services to the community, and (2) to prevent fraudulent medicine—quacks, charlatans and schemers—from exploiting the public.

Any fair and honest analysis of the medical service as provided for the citizens of the United States will demonstrate that the most potential agent for our splendid health record has been the disinterested, unselfish public education that has been carried on by the county and state medical societies and the American Medical Association. A large portion of the funds of these various units of organized medicine has been expended in informing the public of desirable measures for personal and public health. Let me emphasize that a large part of the annual funds of the American Medical Association is expended for the protection and best interest of the public. To specifically name some of these activities, it is only necessary to mention the Council on Medical Education and Hospitals, the Council on Pharmacy and Chemistry, the Council on Physical Therapy, the Committee on Foods, the Bureau of Health and Public Instruction, and the Bureau of Investigation.

So far as organized medicine assuming, as is alleged, a vested interest in sickness, it has through the years brought about a constantly diminishing rate of illness so that it is practically the only big organized function of society that is improving conditions and at the same time lessening its field of remuneration.

It may be pertinent now to inquire whether organized medicine has justified itself. In other words, to look into the record for the purpose of seeing what has been accomplished under the present day set-up of the medical profession. Has the medical service that has been rendered in the past twenty-five years been competent and effective? Has society been rendered free from certain disease? Has the general morbidity and mortality been reduced? Has the general health of the community been improved by medical agencies? It requires but a very cursory survey to arrive at a verdict that medical service has not only been competent but it has been superlatively ef-

fective. Let us draw to your attention that tuberculosis in 1900 had a death rate of 202 per 100,000, while in 1935 it has reached the surprisingly low figure of fifty-five per 100,000, and that out of the seven leading causes of death in 1934-1935, in spite of a period of depression, it showed a fall in mortality ratios. Again, let us take the story of diphtheria. No city in the United States has a death rate more than six per 100,000, yet in fifty-two German cities the rate was eleven per 100,000, and in 151 English cities the rate was 11.6 per 100,000. Typhoid fever, except for certain peculiar areas, has become practically non-existent.

According to the League of Nations Health Statistics, the death rate of the United States in 1934 stood at eleven per 100,000. This death rate includes the Southern states with their large negro population. If we leave out the Southern states and consider that portion of our country that is comparable to Central Europe and the British Isles, we have a death rate less than any country with health insurance. Again, if the causes of death which were operative in 1900 were active today we would have an annual total death of 1,962,999. To the contrary, in 1925, 1,398,673 persons died, a net saving in twenty-five years of 572,326 persons per annum. Our longevity has increased from 47.24 years to 59.31 years, so that we can say that the medical service for the past twenty-five years has not only been effective—it has been extraordinarily competent.

Has the practice of medicine in the last twenty-five years been scientific and in keeping with the general progress in science? A profession that has produced insulin, liver therapy, vitamin therapy, orthopedic and cancer and restorative surgery, and advanced in x-ray diagnosis, and x-ray and radium therapy, has certainly been so productive in discovery as to be well in advance of any of the divisions of physical science.

Has the distribution of medical service been effective? It must be admitted that in our country there are some geographical inadequacies of medical service but I think it may be stated safely that the deficiencies of distribution of medical services are not at all comparable with the illiteracy that exists in some of the backward areas nor with the inadequacy of nourishment, living condi-

Economics

ORGANIZED MEDICINE

CHAS GORDON HEYD, B A, M D, F A C S, *New York City*

New York Post-Graduate Medical School, Columbia University

In the first paragraph of the Oath of Hippocrates every physician swears that "by precept, lecture and every other mode of instruction I will impart a knowledge of the art to my own sons and those of my teachers" Some 2400 years ago was thus laid down the foundation of what has since been called "organized medicine." The transmission of medical knowledge, the acceptance of new discoveries in science, and the obligation to maintain medical services for the benefit of the community have been the outstanding and guiding principles of medical organization.

Organized medicine may be defined as the grouping of physicians in the county and state medical societies and the American Medical Association for the purpose of serving society. Physicians became organized almost from the beginning of time. Historically there are nine epochs in the development of mankind (1) the period represented by the discovery and utilization of fire, (2) the period of the bow and arrow, (3) the period of pottery. These three epochs are roughly called the age of savagery (4) The period of the domestication of animals, (5) the period of metallurgy, (6) the period of writing. These three epochs are roughly called the age of barbarism (7) The period represented by the discovery of gunpowder, (8) the period of the steam engine, (9) the conquest of nature by physical science. These are also roughly grouped together and called the age of civilization.

It is pleasant to reflect upon these various periods, to realize that in all of them there were one or more individuals who treated disease and the injuries of mankind and contributed to the distribution of medical knowledge. It is certain that there was a definite organization of medical men at about 2500 B C for we have in the code

of Hammurabi the record of certain rules that were enjoined upon the medical profession. The history of Greece before the Christian Era is replete with references to groups of physicians and it seems evident that in the formulation of the Hippocratic Oath and the devising of the Hippocratic laws the physicians subscribed to a compact which made their society a model of organized medicine. While Eastern Roman civilization was destroyed by the fall of Byzantium to the Turks in 1453, other events in medical organization were being initiated elsewhere. A medical school was established at Salerno, Paracelsus and Luther broke with authority, Paré introduced the physiologic principle of natural repair in war wounds and Harvey in England was discovering the circulation of the blood.

It is significant that the impetus for medical organization began in England and in France. The Royal College of Surgeons of London was established in 1800 and the French Academy in 1792, while as early as 1760 the General Assembly of New York ordained "No person whatsoever shall practice as a physician or surgeon in the City of New York before he shall be examined in physic and surgery."

The Medical Society of the County of New York was organized on November 14, 1794, two years after Jenner discovered vaccination and three months after the reign of terror in France was brought to an end by the fall of Robespierre. Twelve years later the Society was incorporated on April 4, 1806, a year after Jefferson had been re-elected President of the United States.

In 1807 the Medical Society of the State of New York was founded and authorized to conduct examinations and license applicants for admission to the practice of medicine. In 1847 delegates for the American Medical Association met in Philadelphia and

nese to the practice of medicine does mean progress. Organized medicine welcomes any scientific fact, discovery, survey, research, that will improve the health and well-being of our people. It is not prepared, however, to surrender what has been proved to be good and effective, for a chimerical system involving a complete renovation of medical practice no matter under what shibboleth it is labeled.

There are certain things that do not change with the times. One of these is truth that cannot be in two different places at the same time. Because a thing is, does not necessarily mean that it is fundamentally wrong and mere movement does not mean progress. Medical practice is not a static principle but a dynamic concept of service to the community for the taking care of the physical and mental condition of society. By constantly accepting the advances in science organized medicine has accelerated the health of the people and reduced the measure of illness. Organized medicine believes that it is by this dynamic quality of scientific progress that good medical practice has been given and will continue to improve, and that fundamentally the question is quality of medical service and not cost of medical service.

We believe (1) that all features of medical service in any method of medical practice should be under the control of the medical profession. No other body or individual is legally or educationally equipped to exercise such control.

(2) That no third party should be permitted to come between the patient and his physician in any medical relation. All the responsibility for the character of medical service must be borne by the profession.

(3) That patients must have absolute freedom to choose a legally qualified doctor of medicine who will serve them from among all those qualified to practice and who are willing to give service.

(4) That the method of giving the service must retain a permanent, confidential relation between the patient and a physician. This relation must be the fundamental and dominating feature of any system.

(5) That the medical phases of all institutional service should be under professional control, it being understood that hospital service and medical service should be considered separately. These institutions are but expansions of the equipment of the

physician. He is the only one whom the laws of all nations recognize as competent to use them in the delivery of service. The medical profession alone can determine the adequacy and character of such institutions. Their value depends on their operation according to medical standards.

(6) That in whatever way the cost of medical service may be distributed, it should be paid for by the patient in accordance with his income status and in a manner that is mutually satisfactory.

(7) That medical service must have no connection with any cash indemnity benefits.

(8) That any form of medical service should include within its scope all legally qualified doctors of medicine of the locality covered by its operation who wish to give service under the conditions established.

(9) That systems for the relief of low income classes should be limited strictly to those below the "comfort level" standard of incomes.

(10) That there should be no restrictions on treatment or prescribing not formulated and enforced by the organized medical profession.

Let the critics of organized medicine tell us wherein these ten points are fallacious, and add, if they will, how they fail to safeguard the community in the distribution of medical services.

The insurance principle as applied to human sickness is acceptable only in buying hospital lodging, accommodations, food, and general nursing care. The insurance principle applied to the employment of professional services will fail because there are inherent in it defects that depend upon the variability of human beings. Medical service is not a mechanical gadget that can be fabricated. Medical service is the relationship of a doctor and a patient, both are animated human individuals, both are equipped with their own personal psychology and the character of the medical service rendered is the application of scientific knowledge plus certain intangibles to the patient's medical problem plus the ability and psychology and sympathetic contact of the doctor. This is not an insurance proposition that can be calculated or estimated upon an actuarial basis.

Human nature being what it is the adoption of the insurance principle for medical services puts a premium on malingering and

tions, and housing. In addition, it might quite well be challenged whether the distribution of medical services can be adequate for certain areas until the basic defects of education have been overcome, until more roads are built, the sparsity of population overcome, and the needs of some remote groups of citizens aided by effective contacts with scientific medicine. Remember that hospital facilities have been increased and diagnostic, and treatment clinics far surpass in number and effectiveness the dreams of any sociologist of 1900. I think organized medicine may claim that in general there has been an effective and only exceptionally an inadequate distribution of medical services.

Is the diagnostic work in America superior to that enjoyed by other less fortunate countries? In 1884, there was introduced into Germany by Bismarck a form of socialized medicine called the "Krankenkasse," and in 1911 in England the so-called "Panel System" was inaugurated. From whatever angle one surveys the present medical service in America and compares it with either one of these socialized systems, we find that the American people enjoy better health, live longer, are being born with better health and that our young children are growing up into better specimens of adults.

The outstanding defect of both of the foreign systems is that they divide the practice of medicine into a class practice and the measure of effectiveness of the medical service is dependent upon the economic status of the patient. There is thus created a superior type of medical service for the well to do, and a substandard type of medical practice for those in the lower economic brackets. The practice of medicine in the lower economic group becomes largely a prescription practice—a brief visit to the doctor, a scant short history, and a prescription or the dispensing of a bottle of medicine. One of the most tremendous steps in the practice of medicine in America is that it has become a diagnostic practice, a practice based upon a complete physical examination, scientific laboratory determinations, and the direct opposite of a prescription form of medical practice.

Today, the patient, regardless of economic status has free choice of his physician. Some of our critics maintain that when a patient comes to a hospital he may not choose his

doctor and therefore does not exercise free choice. That is quite beside the question. When a patient goes to a clinic in the City of New York he selects that clinic of his own free will and choice. He is attracted to that particular hospital by its reputation, a reputation founded solely upon the professional service it renders to the community. No authority to date makes that patient go to a particular hospital. He has absolutely unqualified choice as to what hospital he will go to and the doctors he selects are on the basis of the professional service rendered by that hospital. Our medical service under organized medicine at the present time admits of no administrative costs and is without the interposition of a bureaucratic third party between the patient and the doctor.

Has organized medicine improved medical standards and medical education? Improvements in medical education and the measures for protecting the community from inferior practitioners have arisen from within organized medicine. The Medical Society of the County of New York, together with the sixty-one other County Medical Societies, constitute the Medical Society of the State of New York, and the forty-eight State Medical Societies, plus Alaska, Porto Rico, the District of Columbia, the Panama Canal Zone, the Philippine Islands, and Hawaii, constitute the American Medical Association. The organized medical profession as represented by the A.M.A. has brought about a reduction in the number of medical schools from one hundred sixty-five to sixty-seven, and succeeded in obtaining an almost uniform premedical curriculum, has surveyed and approved hospitals throughout the United States, has listed hospitals for the training of interns and resident interns, has promulgated a code of ethics for the protection of the public, has established certification boards for the examination and registration of those seeking to be specialists in all the major branches of medicine. The record shows that the organized profession through its medical societies and under the leadership of the American Medical Association has fulfilled its obligation to society, to go forward in effectiveness and in scientific progress.

Mere changes do not necessarily mean progress but the orderly organization of demonstrable facts and the application of

ase to the practice of medicine does mean progress. Organized medicine welcomes any scientific fact, discovery, survey, research, that will improve the health and well-being of our people. It is not prepared, however, to surrender what has been proved to be good and effective, for a chimerical system involving a complete renovation of medical practice no matter under what shibboleth it is labeled.

There are certain things that do not change with the times. One of these is truth that cannot be in two different places at the same time. Because a thing is, does not necessarily mean that it is fundamentally wrong and mere movement does not mean progress. Medical practice is not a static principle but a dynamic concept of service to the community for the taking care of the physical and mental condition of society. By constantly accepting the advances in science organized medicine has accelerated the health of the people and reduced the measure of illness. Organized medicine believes that it is by this dynamic quality of scientific progress that good medical practice has been given and will continue to improve, and that fundamentally the question is quality of medical service and not cost of medical service.

We believe (1) that all features of medical service in any method of medical practice should be under the control of the medical profession. No other body or individual is legally or educationally equipped to exercise such control.

(2) That no third party should be permitted to come between the patient and his physician in any medical relation. All the responsibility for the character of medical service must be borne by the profession.

(3) That patients must have absolute freedom to choose a legally qualified doctor of medicine who will serve them from among all those qualified to practice and who are willing to give service.

(4) That the method of giving the service must retain a permanent, confidential relation between the patient and a physician. This relation must be the fundamental and dominating feature of any system.

(5) That the medical phases of all institutional service should be under professional control, it being understood that hospital service and medical service should be considered separately. These institutions are but expansions of the equipment of the

physician. He is the only one whom the laws of all nations recognize as competent to use them in the delivery of service. The medical profession alone can determine the adequacy and character of such institutions. Their value depends on their operation according to medical standards.

(6) That in whatever way the cost of medical service may be distributed, it should be paid for by the patient in accordance with his income status and in a manner that is mutually satisfactory.

(7) That medical service must have no connection with any cash indemnity benefits.

(8) That any form of medical service should include within its scope all legally qualified doctors of medicine of the locality covered by its operation who wish to give service under the conditions established.

(9) That systems for the relief of low income classes should be limited strictly to those below the "comfort level" standard of incomes.

(10) That there should be no restrictions on treatment or prescribing not formulated and enforced by the organized medical profession.

Let the critics of organized medicine tell us wherein these ten points are fallacious, and add, if they will, how they fail to safeguard the community in the distribution of medical services.

The insurance principle as applied to human sickness is acceptable only in buying hospital lodging, accommodations, food, and general nursing care. The insurance principle applied to the employment of professional services will fail because there are inherent in it defects that depend upon the variability of human beings. Medical service is not a mechanical gadget that can be fabricated. Medical service is the relationship of a doctor and a patient, both are animated human individuals, both are equipped with their own personal psychology and the character of the medical service rendered is the application of scientific knowledge plus certain intangibles to the patient's medical problem plus the ability and psychology and sympathetic contact of the doctor. This is not an insurance proposition that can be calculated or estimated upon an actuarial basis.

Human nature being what it is the adoption of the insurance principle for medical services puts a premium on malingering and

extension of days of illness. The average loss of time to a workman in the United States by illness is six and one-half days, in Germany under the Krankenkasse thirteen days, and in England under the Panel System eleven and one-half days. The expense of administration of sickness insurance in England amounts to over one-half of the total amount paid to the physicians and the number of nonmedical workers in Germany is greater than the total number of physicians doing the medical work.

No patient should have cash benefits for being sick. Is it reasonable to suppose that a man being sick, not working, in a hospital, being supplied with the physical accommodations and food and attention, and \$4 00 a day while being sick, will be anxious to return to work?

It has been estimated that to provide a comparable medical service such as exists today, on a government insurance basis would require at least ten per cent of the payroll.

It would seem from an earnest study that the medical conditions in our less populous states are not comparable to those that exist in New York State. Personally, I favor a reduction in the number of medical graduates. In 1905 we graduated 5606 physicians from approximately 160 medical schools. In 1935 we graduated from recognized medical schools 5101 physicians and probably between 200 and 300 were graduated from unrecognized commercial schools. We lose by death every year about 3800 physicians—a yearly increase of about 1200 practitioners of medicine.

In November 1929, I had occasion to present certain views upon the distribution of medical services. These views were advanced three years before the final report of the Committee on the Cost of Medical Care. In the intervening seven years, while I have had occasion to modify the practical details of these suggestions, I believe that they are fundamentally sound and are applicable to the medical profession of the City of New York, or in a larger way to the State of New York. I again offer them with some added details as a practical, sincere, and honest attempt to increase the usefulness of the medical profession and to give a wider application to all medical services.

Every practitioner believes that the proved indigent is entitled to medical serv-

ices free of all charges and that the cost of this service should be paid by taxes levied on the general population. The maintenance of this service is a responsibility of the State and not the Federal government, although the Federal government might remit sufficient funds if and when necessary to make up the deficit. For this service it would be necessary to define economic indigency and medical indigency. We believe that it is essential that the following conditions be made paramount in the consideration of medical services:

1 The maintenance of the voluntary hospital system with its free initiative, its independence, its spirit of research, and its unfailing services to the community.

2 The extension of medical services to the indigents in their homes and the doctors' offices with remuneration to the physicians on a capitation basis under the direction of the County Medical Society. All free services to indigents to be rendered by the physicians or outpatient department of the hospital within the geographical or regional zone in which the indigent resides.

3 The payment of a fair remuneration to all physicians working in outpatient departments or giving medical services to the indigents in their homes. This remuneration must not be so low as to bring with it an inferior medical practice and the palliative bottle of medicine. It should not be too high. *A fair average can be worked out and still maintain the best qualities of scientific medicine.* In the planning of the details of this service it might seem wise to set up a special subdivision of activity under the auspices of the County Medical Society and with a medical service bureau. This bureau would function along the lines evolved in creating the Workmen's Compensation Bureau of the Medical Society of the County of New York.

4 The complete financial separation of the free outpatient department of hospitals from the private or pay services of the hospital.

5 Limitation of the number of patients that may attend any one clinic. Since it is claimed that there is no profit in clinic and outpatient department services there should be no desire for a hospital to increase the number of outpatients beyond its capacity to take care of them. To save valuable time, with the economic loss, clinics could be run with a limited number and on an appointment basis.

6 Certification of indigents, fairly, sincerely, honestly, and sympathetically by the application of standards of eligibility, by central bureaus under the Department of Welfare with proper representation from the County Medical Society. It should not be the function of the out-

patient department to pass upon the validity of indigents nor should they admit for free services those that are not in truth indigents

7 Medical census of the indigents—to learn what our load is and how to take care of it. There should be devised a positive means of identification to prevent padding of the lists

8 Unequivocal opposition to all forms of compulsory health insurance. Insurance schemes tend to relieve the individual of his own responsibility and to increase the prolongation of illness. In short, under an insurance scheme it is profitable for an individual to be sick.

It seems to me that these are not unattainable objectives but can be brought into being by a mutual consideration of the problems between the various parties interested and organized medicine.

A constantly recurring enigma seems to be—why some altruistically minded individuals in high office apparently wish to foist upon an inadequately informed American people a system of medical practice of demonstrably inferior quality and at a constantly increasing cost, with a huge extension of administrative expense—all this to be paid for by invisible or indirect taxation. Why substitute this for a tried and

functionating, adequate, good medical service, distributed at the present time at a surprisingly low cost and without bureaucratic or political administration I know of no way to judge the future except by the experience of the past. Why should we discard all of our experience and enter upon a path of trial and error and which eventually leads to a poorhouse medical practice

Finally, may I, to paraphrase the words of a distinguished statesman, state that the medical profession "does not rely on endowment, but on its own exertions directed to meeting human wants. There is no great profession which has so little to say to the public purse, and which so moderately and modestly dips its hand into that purse. It is not only in the interest of the public, but of the profession itself, that it is eminently self-supporting, and, rely upon it, that the principle of self-support does much to maintain its honour and independence, and to enable it to pursue its stately march in the times that have come and in the times that are coming, to form its own convictions, to act upon its own principles without fear or favor, for the general benefit of mankind"

THE DOCTOR OF TOMORROW

DWIGHT ANDERSON

Director, Public Relations Bureau Medical Society of the State of New York

The Doctor of Today has been summoned before the court of public opinion. He is accused of failure to make his services available to all the people who need them. It is alleged that he is indifferent to the sufferings of those who are deprived of medical care because they are unable to pay for it. Government-controlled health insurance is to bring together the impoverished sick and the idle doctors.

It is an historic scene we are witnessing. On the issue of this trial of the Doctor of Today will depend the fate of the Doctor of Tomorrow. In this connection the words of Schiller come to mind "For in today already walks tomorrow." In the past centuries of the doctor's tradition, as he struggled to make a scientific art out of a superstitious necromancy, no such

charge was ever lodged against him. Not until we reach the present age, in the plenitude of a civilization surfeited with too much of everything, do we find him accused of not giving enough, of withholding his services. So now he comes to trial.

I am going to try to picture the scene on this occasion assuming that I have been selected to act as the doctor's advocate. The jury consists of six men and six women. Some of them have been patients of the doctor. Two were so poor they could pay for nothing, and the doctor took care of them free. Two of them could pay him, but have not. Two others do not believe in doctors and are a little bored to have to serve on the case. The remaining six have been patients at one time or another. All

Delivered before the 116th Annual Meeting of the Medical Society of the County of Monroe, Rochester, December 15, 1936

are typical American citizens a chauffeur, a silkmerchant, a lawyer, a college professor, a clerk, a retired business man, and among the women, a stenographer, a milliner, a telephone operator, a burlesque strip-dancer, a clubwoman, and a housewife

The jury has heard the testimony There were four witnesses a social worker, a sociologist, a professional uplifter, and a politician It could be seen that the evidence they presented, though it was mainly hearsay, produced a profound emotional effect upon the jury The witnesses were apparently disinterested They made strong claims in behalf of the underprivileged, alleging that women everywhere were dying for lack of medical care while the doctor sat idly twirling his thumbs in his office They pictured children suffering from disease and defects while the doctor spent his idle time on a golf course, careless of their suffering

The prosecution's case was well-presented because it was heavily financed Contributions had been made by a few large employers of labor who wished to give their employees cheap medical care instead of higher wages Pressure had been brought to bear by politicians convinced that nothing in the country was conducted as well as they could run it if given a chance Thousands of jobs and millions in perquisites were to be the prize if they could get the doctor under their control His occupation, economically, rated as the third in magnitude in the land

So the thing the jury was called upon to decide was whether the doctor was to be forced to work for the politicians under a system of health insurance conducted by the state, and paid for by contributions from the state augmented by a sickness tax levied on the employee and the employer

In his defense the doctor summoned, for the most part, other doctors They were men of the highest standing in their profession But it was easy to see that the jury was unconvinced, that they regarded this testimony as self-serving Only one non-medical witness, J Weston Walch, a school-teacher, went on the witness stand in a pamphlet which he wrote with that title The jury paid close attention to what was said by this unbiased student.

In rebuttal, the prosecution called a physician who had spent most of his life

in academic work, far from the actual practice of his profession He presented the problem not in terms of actual human behavior as the plan would work out in practice but in the form of figures, charts, and designs on a sheet of paper Nevertheless, his testimony weighed heavily with the jury who knew nothing of the elemental human values of confidence and trust which contribute to the success or failure of the therapeutic relationship

So it is at this juncture that the case is closed, and the time comes in the course of things for the doctor's advocate to rise in his place and address the jury

And were I to be his advocate I should argue like this in the court of public opinion

"You see before you here today a man not to be judged as other men are judged. His habits of life have led him to tincture his idealism with realism He is a man addicted to facts He has mistakenly thought, until now, that his best arguments would be the universal knowledge of the millions whom he has served without charge, the discoveries he has perfected and given without pay to the world, the efforts he has made to discipline himself and his brothers to the highest perfection of which they are capable. He has not thought the issue would be decided by the contestant who could shout the loudest So he appears here unprepared In fact, it was not until the last moment before the case was called, that he bethought himself to find an advocate.

"In his defense you have heard evidence that in countries where this scheme has been in operation vital statistics fail to show health conditions as good as in our own land, the healthiest in the world. But the answer comes that the plan might work better in this country than in England or Germany We asked and failed to get an answer, whether government here had proved itself able to administer affairs, even as well as in those European countries where health insurance has dismally failed to produce conditions as favorable as already exist in America

"The substance of the doctor's defense is that he cannot do his best work under health insurance, whose incentives and rewards will be alien to the attainment of excellence. The doctor submits that doing less than his best will effect a gradual de

January 15, 1937]

terorization of his character, lowering the quality of medical service. Obviously nobody wants this. Here, then, is a sharp conflict of opinion. The witnesses on the other side, who are not doctors, can see no reason why this should be so. We contend that if they were doctors they could see it. On this clear-cut issue you are forced to decide which view is most likely to be right.

"Now I ask you to decide that the doctor is most likely to be right because of all that you know about him. Certainly he has the best reason to be right, spending his life in care of the sick. You see him constantly trying to eliminate the causes of disease, knowing full well that the greater his success the less will be the demand and the pay for his services. Now if his opposition were affected by his financial interest would not this grasping attitude be reflected in other things that he does? Would he not patent his discoveries and sell them at a high price? Would he not demand pay in advance everywhere he goes? Having the power to heal, and having, at the moment of greatest suffering and anxiety, when he is first called, the opportunity to exploit the sick, why does he not do so, if he is the type of man to think first of his own selfish interest? If money alone were his aim would he spend it for post-graduate education to better discipline himself to serve you? Would he advocate always those measures, in the profession and out of it, which make it more difficult to become and to remain a doctor, to the end that the bungler, the incompetent, and the mercenary may not impose on the credulity of the sick under the sanction or the superiority which the title of physician gives him? Yes, there is self-interest here, of the sort that is contained in the struggle for perfection, but it is the kind of self-interest which protects the public more than it protects the doctor.

"When your life is in danger through sickness you place your entire being unreservedly in his hands with full confidence in his ability. Don't you think he is worthy of trust in deciding this matter? Don't you think he *must* know, better than anyone else, when he says that this scheme will make it impossible for him to render you full service, impossible for him to continue to be as worthy of your confidence as he is now? Who knows any better than he

does what will happen to him, and by the same token, what will happen to you? Certainly none of the other witnesses you have heard are likely to know so well. They cannot see the situation as realistically as he does because they are not men actively engaged in giving medical care to people.

"This is a bauble gift which is offered you. It will vanish at the touch. There is no substance in it. It is a part of the corrupting psychology of the day that we can get something for nothing, that life can be made easier than Nature intended it to be. Few have the courage to say with Cassius, 'The fault, dear Brutus, is not in our stars, but in ourselves, that we are underlings.' During the difficult recent years the ego of the crowd has been unable to bear the knowledge of its incapacity to walk on its own feet, and so there must be a scapegoat. The demagogue began to feed the crowd the flattery which it has loved to hear throughout all ages of history. The people were given 'panem et circenses.' The mob was fired with zeal to find, and to punish, those who had brought about their confusion and despair. Now, today, in this forum of public opinion, the doctor is the last of these scapegoats to be put into the dock. If you decide against him, it will not be the first time that the world has turned against its real benefactors.

"You have been told that many are without medical care, but you have not been told how many. The statistician who testified showed you figures that more than ninety per cent of the people who were questioned in a survey covering a certain year, were able to obtain medical care. Yet the statistician did nothing to find out why less than ten per cent went without it. That question was not asked. There is no evidence before you whatever that anyone seeking medical care was denied it.

"Members of the jury, you cannot be healed unless you seek to be healed. A system of medical care cannot be forced upon you to good purpose. It cannot be, and it should not be, brought to you without effort or sacrifice on your part. Its acceptance by you will be measured by the value which you put on it, and having given little, you will receive little. This is a law which cannot be escaped. It is with the illness of the flesh as with that of the spirit. 'Seek and ye shall find.'

"Ladies and gentlemen of the jury, the

fate of the doctor is in your hands. You can make him master of his house, or servant in the house of another. But whether he be master or servant he will still try to heal the sick, for such is his nature, different than that of other men. Healing has been his chief concern since the early dawn of recorded history. It is his chief concern today. It will be his chief concern tomorrow. Take his tools away and still he will seek to heal the sick. Relax his disciplines, and still he will seek to heal the sick. Put over him a clerk to dictate his prescriptions, a supervisor to interfere with his diagnosis, he will yet attempt to heal the sick. History recounts that the long list of physicians who ranked high in favor of the public for achievements in other walks of life were doctors first, and second they might be governors, as John Winthrop of Connecticut, or William Bull of South Carolina, or soldiers, as Leonard Wood, Walter Reed, and William C. Gorgas, members of the Continental Congress and a signer of Declaration of Independence as Benjamin Rush, authors as Oliver Wendell Holmes and S. Weir Mitchell, an etcher as Sir Seymour Haden, or a social reformer as Rudolph Virchow, and still their first concern has been the healing of the sick.

"In the second century many a great Roman relied upon the good offices of a medical slave, and though the Doctor of Tomorrow become your slave he will be healing you. In the darkness of the middle ages, with his skill taken from him in ways different from, but in effect similar to what you are asked to do to him now, nevertheless, he tried to heal the sick. We find him as Guy de Chauliac, chaplain and physician to three popes in the fourteenth century, we find him as Francois Rabelais in the fifteenth century, author and physician, later, in the seventeenth we find him as Thomas Sydenham, a puritan captain of horse in the Civil Wars, but his first concern was to heal the sick. In our own time, Sun Yat Sen and Georges Clemenceau offer plenty of proof that the physician, drawn aside to other paths in life, retains a native instinct to bind up the wounds which society inflicts upon itself, even when the wounds are sustained in contests against such wise leadership as the physician himself represents.

"Perhaps the physician is now to pay the penalty which is often exacted of honest

men. It is said that 'Glad are the feet of him who brings good tidings.' But the doctor recognizes the charlatan in many an optimist. The doctor knows that sickness, accident, and death must come to all of us. He knows that he who seeks to moderate the cruelty of these ills must work hard for this accomplishment. He knows that life is meant to be difficult, that rewards are meant to have their price, that things ought not to be made to seem easier than they really are. He has had the courage to tell you this, in the very teeth of the quack who would make you think that you are underprivileged. He knows that nature has been working for millions of years to make man fit to pay a great price to insure his own existence, and that the *best health insurance that can ever be obtained is that which comes individually by struggling to get it*. The doctor knows, and he has said, that mankind cannot rely for self improvement upon mere legislation put into operation by a beneficent government. The doctor knows that the man of yesterday, today, and tomorrow, is lost who depends for his salvation on giving less to society in order to get more. His advice has been frequently unpleasant, his instructions often entailed personal effort and self-denial, his warnings on occasion have been ominous. His feet were not always glad.

"He has had the courage to tell you these things in the face of the popular clamor that some mysterious force has stolen your birthright, which the magi will now return to you.

"He has had the courage to tell you these things because they are the truth. Ever he has sought the truth about life and death. He is different than other men. He is not to be judged by the standards of other men. He will not bring you good tidings for the pleasure of seeing your faces beam with pleasure, unless they are true tidings. For he knows that this is only to pander to a worse ailment than any we are trying to remedy, inducing false hopes which can be cured only by the ultimate tragedy of disillusionment. As is his way, he has told you the truth that life is hard, the way to the hilltop long and steep and difficult. For his plain speaking it is possible that you may condemn him, for he has been condemned by others before because he did not applaud ignorant altruism, change which was not progress.

"But no matter what you do to him, he heals the sick today and will still heal them tomorrow 'For in today already walks tomorrow' Under socialism, dictatorship, monarchy, despotism, or democracy still he will heal the sick, as best he can If you try to pluck him by the arm, he will pull himself away to keep on in the path he has chosen, though it now be a tortuous one, for he is not as other men are, easily persuaded. You may call after him 'But here is a different way for you to be paid, so you can make more money and heal more people.' His reply will be 'Do not hinder me What do you mean, 'more people?' My hands are full, day and night I care for those who come to me, who need me most and prove it by the act of seeking me. My time belongs to them, not to others who through indifference or ignorance may have no faith in me, though I

run after them I am too busy to experiment with plans and schemes I must heal the sick.'

"Whatever you do to the doctor you can not divest him of this privilege, responsibility, and prerogative which, at long last, is what matters most to him and to you

"So now I leave with you, members of the jury, the fate of the accused. Do with him as you will Do with him as you must, under the law and the evidence, remembering, as you consider your verdict, that it will be as momentous a decision for you as it will be for him, remembering that he brought you into the world and helped to keep you here"

* * *

Thus might the doctor's advocate present his defense at the bar of public opinion

We all await the verdict!

FIRST INTERNATIONAL CONFERENCE ON FEVER THERAPY

The First International Conference on Fever Therapy will hold its sessions on March 29, 30, and 31, at the College of Physicians and Surgeons, Columbia University, New York City The first day will be devoted to the discussion of physiology, pathology, and methods of production of fever Dr Frank W Hartman, Henry Ford Hospital, Detroit, is Chairman of the Committee arranging this section of the program, and Dr Charles A Doan of Ohio State University is Secretary

The second day is to be spent in the consideration of miscellaneous diseases treated by fever, such as chorea, rheumatic carditis, ocular diseases, arthritis, leprosy, meningococcus infections, undulant fever, tuberculosis, tumors, skin diseases, etc. This session will be arranged by Dr Clarence A Neymann, 104 South Michigan Boulevard, Chicago, with the assistance of Dr Frank H Krusen, Mayo Clinic, Rochester, Minnesota, as Secretary

The morning of the third day is to be devoted to the consideration of syphilis Dr

Walter M Simpson, Miami Valley Hospital, Dayton, Ohio, is Chairman of this section, which has as its Secretary Dr Leland E. Hinsie, New York State Psychiatric Institute, New York City In the afternoon of the same day, the treatment of gonorrhea by fever is to be discussed under the chairmanship of Dr Stafford L Warren, Strong Memorial Hospital, University of Rochester, Rochester, N Y The Secretary of this committee is Dr Charles M Carpenter, Rochester, N Y

Those desiring to participate are requested to communicate with the Chairman of the Section in which they are interested The manuscripts of all papers must be submitted to the appropriate chairman before February 1 Selection for the program will be made by February 15

All who plan to attend the Conference are urged to register promptly with the General Secretary, Dr William Bierman, 471 Park Avenue, New York City The registration fee is \$15 00

Schenectady and Utica hold banner positions in the table of deaths from automobile accidents with no "deaths due to accidents in the city" in the four weeks ending Nov 21,

the latest report In the 58 weeks, too, ending on that date, Schenectady had only 10 and Utica only 9 The highest death-rates are in the Pacific Coast cities

PNEUMONIA CONTROL PROGRAM

Prize for Report on Cases of Pneumonia

The Advisory Committee on Pneumonia Control of the New York State Department of Health offers a prize of one hundred dollars for the best report of a series of cases of pneumonia

The competition is open to all physicians residing and practicing in New York State outside of New York City. Interns in hospitals may compete but the report in all cases should include only those cases actually seen and studied by the writer, and should include all cases of pneumonia of all types and forms treated by him either in private practice or in hospitals during the present winter

In awarding the prize less stress will be laid upon the number of cases than upon the objectivity exhibited by the writer in his description of the cases and upon the originality and independence shown in the interpretation of the clinical features. Credit will be given for the extent to which the newer methods of diagnosis and treatment of cases of lobar pneumonia were employed. If the writer desires, the report may be documented by full clinical histories and laboratory reports, but the report itself should not be longer than 5,000 words and be in a form suitable for publication in the NEW YORK STATE JOURNAL OF MEDICINE

Reports should be in the hands of the Committee not later than August 15 and the award will be made October 1

Address further inquiry to

Dr. Edward S. Rogers,
Director, Bureau of Pneumonia Control,
New York State Department of Health,
Albany, N. Y.

Medical News

Secretaries of County and local Medical Societies are requested to send the programs of coming meetings to this department one month in advance, for the information of members who may be interested

Albany County

DR CHARLES A PERRY, head of the medical department of Memorial Hospital, has been elected president of the Medical Society of the County of Albany. A native of Rome, Dr Perry received his professional education in Albany Medical College, graduating in 1914.

During the World War he served as medical officer in the Quartermaster Corps at New York City. After his discharge he started practice in Albany.

Others elected include Dr Otto A Faust, vice-president, Dr Homer L. Nehms, secretary, Dr Francis E Vosburgh, treasurer, Dr Raymond R Kireher, Dr Arthur M Dickinson, Dr William Rausch, Dr John E Heslin and Dr James S Lyons, censors, Dr Edgar A VanderVeer, Dr Frederick C Conway and Dr William P Howard, delegates, and Dr John J Clemmer, Dr Arthur J Wallingford and Dr C W Louis Hacker, alternates.

Bronx County

DR FOSTER FANNING POTTER, who had practiced medicine in Harlem and the Bronx for more than fifty years, died on Dec 18, after a few days' illness of pneumonia. He was in his eighty-fourth year.

Dr Potter had specialized in gynecology. He practiced in Harlem until about twenty years ago, when he moved to the University Heights section of the Bronx. He founded the Harlem School of Nursing in 1906.

THE "ANNUAL AFFAIR" of the Bronx County Medical Society will be held on Sunday, Jan 24, at 10 30 P M at the French Casino, 7th Ave and 50th St. Dress will be informal and tickets will be \$5 per person. Supper, dancing, and a show will be provided. The proceeds will go to the society's relief fund and the Physicians' Home.

Broome County

Following is a list of officers elected at the annual election December 8 of the Broome County Medical Society, reported by the Secretary, Dr Henry D Watson.

President, S M Allerton, Vice-President, Charles L Pope, Secretary, Victor W

Bergstrom, Treasurer, E R Dickson, Secretary Emeritus, Henry D Watson, Assistant Secretary, Rollin C Bates, Assistant Treasurer, E M Jones.

Censors: C M Allaben, S B Blakely, J J Cunningham, S D Molyneaux, C D Squires. Compensation Board: Blinn A Buell, D G Dudley and F M Miller.

Delegates: S M Allerton and G C Vogt. Alternate Delegates: P H Shaw and C H Lopping. Chairman Economic Committee, H I Johnston, Chairman Legislative Committee, C J Longstreet, Chairman Public Relations Committee, Blinn A Buell, Chairman Library Committee, S B Blakely, Chairman Membership Committee, C H Berlinghof, Chairman Milk Commission, P H Shaw, Chairman Public Health, Geo S Lape.

Cayuga County

DR DONALD M GREEN of Auburn was elected president of the Cayuga County Medical Society at its annual election of officers and banquet held in the Hotel Osborne on Dec 17. Dr L D Burlington was voted vice president, Dr S J Karpinski, secretary, and Dr W A Tucker, treasurer.

Dr G C Sincerbeaux, Dr H S Bull, Dr R C Almy, Dr W B Wilson, and Dr C T Yarrington were elected to the Board of Censors. Dr H S Bull was named as delegate to the State Medical Society convention with Dr G Perry Ross as alternate. Dr A K Bates was elected delegate to the Seventh District Branch of the Medical Society session with Dr H I Davenport as alternate.

The Medical Society went on record as strongly recommending the immediate vaccination of all children as a precautionary measure against the small-pox epidemic now appearing in Western New York.

Doctor Sincerbeaux, past president of the society, presided at the meeting and introduced the guest speaker, Dr Leonard Carmichael, dean of the College of Liberal Arts at the University of Rochester. Doctor Carmichael's topic was "The Psychology of Genius."

A social session, with dancing and bridge, followed the meeting.

PNEUMONIA CONTROL PROGRAM

Prize for Report on Cases of Pneumonia

The Advisory Committee on Pneumonia Control of the New York State Department of Health offers a prize of one hundred dollars for the best report of a series of cases of pneumonia

The competition is open to all physicians residing and practicing in New York State outside of New York City. Interns in hospitals may compete but the report in all cases should include only those cases actually seen and studied by the writer, and should include all cases of pneumonia of all types and forms treated by him either in private practice or in hospitals during the present winter.

In awarding the prize less stress will be laid upon the number of cases than upon the objectivity exhibited by the writer in his description of the cases and upon the originality and independence shown in the interpretation of the clinical features. Credit will be given for the extent to which the newer methods of diagnosis and treatment of cases of lobar pneumonia were employed. If the writer desires, the report may be documented by full clinical histories and laboratory reports, but the report itself should not be longer than 5,000 words and be in a form suitable for publication in the *NEW YORK STATE JOURNAL OF MEDICINE*.

Reports should be in the hands of the Committee not later than August 15 and the award will be made October 1.

Address further inquiry to

Dr. Edward S. Rogers,
Director, Bureau of Pneumonia Control,
New York State Department of Health,
Albany, N. Y.

At the scientific session, Dr Tasker Howard explained autopsy procedures at hospitals, Dr Newton Thomas Saxl discussed the activities of the Police Athletic League of which he is medical director, and Dr Morris Fishbein, editor of the *Journal of the American Medical Association*, spoke on new forms of medical practice.

An ophthalmological exhibit was presented to the society by the Central Medical Council in honor of Dr Joachim, retiring president.

Other officers elected were Drs Augustus L Harris, vice president, Joseph Raphael, secretary, Thomas B Wood, assistant secretary, Maurice J Dattelbaum, treasurer, Arthur C Holzman, assistant treasurer, J C Rushmore, librarian, and Edwin P Maynard Jr, curator.

Trustees chosen were Drs Frank L Babbott, William Browning and Henry Joachim. New censors are Drs Charles A Anderson, Eugene R. Marzullo, William C Meagher and Joseph Rosenthal.

THE WOMAN'S AUXILIARY TO THE Medical Society of the County of Kings held its annual meeting for the election of officers and Christmas celebration on Dec 8 at the Medical Society Building. The officers re-elected were Mrs Griffin, president, Mrs S Lloyd Fisher, first vice president, Mrs Frederick E Elliott, second vice president, Mrs Milton B Bergman, recording secretary, Mrs Louis Harris, associate secretary, Mrs George H Smith, treasurer, Mrs Milton I Strahl, associate treasurer, Mrs James Steel and Mrs Irving J Sands, directors for three years. The delegates to the State convention are Mrs Charles Goodrich, Mrs Irving Sands and Mrs Charles Gordon.

Delegates and alternates elected to the convention at Rochester, N Y, next May are Mrs William E Lippold, Mrs Marius Abbene, Mrs W Reynolds Shetterly, Mrs George H Smith, Mrs Charles Scofield, Mrs Joseph L'Episcopo, Mrs John J Black, Mrs Louis Harris, Mrs Paul C Eschweiler and Mrs Philip Lombard.

THE FOLLOWING ARE THE newly elected officers of the Section on Physical Therapy, Kings County Medical Society, for 1937: President, Samuel A Warshaw, M D, vice-president, Nathan Goldstein, M D, secretary, H Tevel Zankel, M D, board of governors, Charles Francis McCarthy, M D, John Hauff, M D, and Jerome Weiss, M D.

Montgomery County

THE ANNUAL MEETING OF the Medical Society of the County of Montgomery was

held on Dec 9 at Amsterdam, preceded by a complimentary dinner enjoyed by practically the entire membership.

Dr Hicks, chairman of the nominating committee, presented the report of that committee which resulted in the election of the following officers: Dr A J Townley, president, Dr E A Bogdan, vice president, Dr William R. Pierce, secretary, re-elected, Dr S L Homrighouse, treasurer, Dr W H Seward and Dr R C Simpson, and Dr W R Rathbun censors, Dr H M Hicks, delegate to the Medical Society of the State of New York, Dr E. C LaPorte, delegate to the Fourth District branch. Dr Pierce has been secretary for thirty years.

Nassau County

MRS A M BELL was re-elected president of the Ladies' Auxiliary to the Medical Society of Nassau County at its meeting on Dec 15 at the Nassau Hospital auditorium. Other officers for the year will be Mrs L M Lally, first vice president, Mrs Luther Kice, second vice president, Mrs H L Hirsch, recording secretary, Mrs N L Robin, corresponding secretary, and Mrs Quintard Taylor, treasurer. Board members are Mrs P A Williams, Mrs Benjamin W Seaman and Mrs H B Smith.

Delegates to the convention at Rochester in May will be Mrs H F Gillette, Mrs Benjamin W Seaman, Mrs F W Fry, Mrs C J Welge and Mrs A C Martin. Alternates will be Mrs R. E Lease, Mrs W Taylor Chamberlin, Mrs G R Nodine and Mrs N R. Robin.

THE STATUS OF SMALLPOX vaccination in Nassau County is declared "extremely bad" by Dr Howard M Phipps, President of the County Medical Society. He adds "If an outbreak were to occur in Nassau County it would find us with probably not more than ten per cent of our population protected, and one case of virulent type of the disease might start an epidemic such as this county has never seen."

"All persons who have not been vaccinated within the past five years are urged to seek this protection immediately. Certainly the parents of young children should not postpone securing this treatment."

New York County

DR. JOHN HOWARD NORTHRUP, of the Rockefeller Institute for Medical Research, will receive the sixteenth award of the Charles Frederick Chandler Medal of Columbia University, on the centennial of the birth of the founder of the American Chemical Society, it is announced by Dr

Chautauqua County

A "PHYSICIANS' EXCHANGE," similar to those now in operation in many other communities, has been opened and is expected to prove of material advantage to Dunkirk-Fredonia doctors as well as their patients.

When a physician leaves his office during the afternoon or evening, he calls the exchange and states his probable location for the next few hours. Any of his patients who wish to contact him merely call the exchange and the message will be relayed to him immediately.

With this system in force, physicians will feel more at liberty to take time off from their daily routine. Members of the doctors' families or office help will not be required at all times for answering telephone calls.

Cortland County

THE CORTLAND COUNTY Medical Society met on Dec. 18 and elected the following officers: President, Dr. William F. Newcomb, vice president, William A. Shay, secretary, Dr. O. E. White, treasurer, Dr. B. R. Parsons, delegate to state convention, Dr. D. R. Reilly, alternate, Dr. J. E. Wattenberg, board of censors, Dr. J. E. Wattenberg, Dr. C. D. VerNooy, Dr. A. M. Loope, Dr. M. R. French, Dr. C. E. Chapin.

Following the election, Dr. French gave a talk on smallpox, particularly the Dansville-Hornell epidemic.

Erie County

THE ANNUAL ELECTION of the Erie County Medical Society on Dec. 21 resulted in the unanimous choice of Dr. John T. Donovan as president, Dr. Harry C. Guess, vice president, Dr. Louise W. Beamis, secretary, Dr. James L. Gallagher, chairman, legislation committee, Dr. Joseph C. O'Gorman, economics, Dr. Allen R. Long, membership. All were unopposed.

Delegates to the state society were elected as follows: Dr. James H. Borrell, Dr. Guess, Dr. J. Herbert Donnelly, Dr. Thurber Le Win. Alternates are Dr. Roy L. Scott, Dr. John Burke, Dr. Robert E. De Ceu and Dr. W. Warren Britt.

A board of censors, all unopposed, includes Dr. Charles W. Bethune, Dr. Francis E. Fronczak, Dr. Michael A. Sullivan, Dr. Abram L. Weil and Dr. Francis J. Butlak.

Dr. Nelson W. Strohm was elected chairman of the public health committee over Dr. Russell H. Wilcox.

Dr. Mesco J. Helminiak, member of the City Hospital Board of Managers, was de-

feated for second vice president by Dr. Carlton E. Wertz by a vote of 295 to 115, while Dr. William F. Jacobs, hospital pathologist, lost to Dr. Caryl A. Koch in the contest for treasurer by a vote of 283 to 121.

On recommendation of Dr. John H. Evans, professor of anesthesia at the University of Buffalo School of Medicine, who drew up the plan, the members voted approval to the City hospital's proposal to seek a budgetary appropriation of \$17,396 for the school, which would train interns, students of medicine, and practicing physicians in anesthesia.

The proposal calls for a staff of eight resident anesthetists, headed by the University of Buffalo professor of anesthesia at a salary of \$6,000 a year. An assistant chief anesthetist would receive \$4,000 a year and other salaries would range from \$708 to \$924 annually.

The society also voted to constitute its Comitia Minora a board of censorship for all releases to the press, either by the society as a whole or by individual members.

Herkimer County

HERKIMER COUNTY MEDICAL SOCIETY, at its annual meeting and banquet on Dec. 8 elected Dr. J. J. McEvilly, president for the coming year.

Other officers: First vicepresident, Dr. James F. Gallo, second vicepresident, Dr. G. A. Burgin, third vicepresident, Dr. G. J. Frank, secretary, Dr. F. C. Sabin, treasurer, Dr. A. L. Fagan, U. G. Williams was renamed librarian.

The censors chosen are Dr. A. W. Vickers, Dr. H. J. Sheffield, Dr. H. C. Murray, Dr. L. P. Jones, and Dr. H. F. Buckbee. The latter is the retiring president.

Dr. J. J. McEvilly was chosen delegate to the Medical Society state meeting with Dr. Gallo as alternate.

Jefferson County

THE REGULAR MEETING of the Medical Society of Jefferson county was held on Dec. 10 at the Black River Valley club. "The Therapeutic Program at the Saratoga Spa," was the subject of Dr. Walter B. McClelland, medical director of the Saratoga Springs commission.

Kings County

DR. JOHN B. D'ALBORA WAS ELECTED president of the Kings County Medical Society at its annual meeting on Dec. 15. He succeeds Dr. Henry Joachim.

The officers, all of whom took office for the first time last year, are Dr William C Buntin, president, Dr Frederick M Schward, vice-president, Dr John J Goller, secretary, and Dr Curtis J Becker, treasurer. Dr Buntin announced that all present committees would be retained.

Suffolk County

DR. STANLEY P JONES is the new president of the Suffolk County Medical Society, having been elected at the annual meeting held in Riverhead. Dr Jones was first vice-president and succeeds Dr David L MacDonell.

Other officers elected include Dr Earl M McCoy, first vice-president, Dr W W Gardner, second vice-president, Dr Edwin P Kolb, secretary, and Dr Grover A Silliman, treasurer.

Dr Coburn A L Campbell and Dr John L Sengstack were elected delegates to the State convention, and Drs L MacDonell and Earl M McCoy were named delegates to the second district branch.

Censors elected were Drs Paul Nugent, Frank McGilvery, Victor K. Young, Warren Eller, and Leon Barber.

Tompkins County

THE DESTINIES OF THE Tompkins County Medical Society will be guided for the coming year by Dr William F Lee. Doctor Lee was named president at the annual meeting on Dec. 15.

Other officers elected were Dr H J Wilson, vicepresident, Dr B F Hauenstein, secretary-treasurer, Doctors W L Seil, David Robb, H L VanPelt, J W Judd, and V A Van Volkenburgh, censors. Dr Norman S Moore will be delegate to the State Medical Society.

The constitution was amended to read that meetings will be held quarterly instead of monthly.

Wayne County

APPROVAL OF A COUNTY MEDICAL laboratory to be located at Newark State School and a resolution to include the \$1,200 as the county's share of the \$2,400 necessary to operate it, was voted 13 to 1 by Wayne County Board of Supervisors on Dec. 1.

This is considered one of the greatest steps ever made by the county toward better health and increased medical protection. Plan for the laboratory, to be used freely by all doctors in the county, was backed by a committee of the Wayne County Medical Society, headed by Dr F C Donnelly of Newark.

According to Dr Donnelly, establishment of the "lab" will be accomplished at far cheaper cost than any other county has expended for a similar purpose. It will be operated in conjunction with the regular laboratory of the State School, through the generosity of Dr Charles L Vaux, superintendent, and cooperation of Dr Edwin Baumgartner, pathologist.

This lab will be housed in the recently constructed state school hospital building. Cost of maintenance will be \$2,400, of which the state and county will each pay half. This cost will be only for additional help and equipment required in handling tests for doctors of the county.

Dr Donnelly stated that it was one of the best things ever done for Wayne residents. "Heretofore," he said, "physicians who were near enough could take their tests to the state school lab and were accommodated, but the patient had to stand the expense. In cases of poor and needy families, although Dr Baumgartner co-operated 100 per cent in giving many his services gratis, it was becoming harder to take care of them."

"With this new set-up we may have tests made for pneumonia, get the proper serum, and administer it within two or three hours, with recovery starting next day. This is a time saving that may mean the difference between life and death. And the financially poorer class can receive this benefit too."

The new laboratory is completely equipped for nearly every type of test required, tests that often forced doctors to wait several days while they were made by the state health department in Albany. It is expected that one additional assistant will be added to Dr Baumgartner's lab staff and some further equipment purchased to handle tests for doctors.

Westchester County

TECHNICAL DISCUSSIONS OF MEDICAL legislation and compensation laws were heard by sixty members of the Mount Vernon Medical Society at the December meeting. Dr E B Sullivan presided.

Speakers included Dr Frederick E Elliott, chairman of the economic committee of the Medical Society of the State of New York, who spoke on "Problems in Medical Economics", Dr David J Kaliski, chairman of the committee on workmen's compensation of the New York Medical Society, whose subject was "The Workmen's Compensation Law," and Dr John B Lauricella, medical director of the State Insurance Fund, who discussed "The Compensation Insurance Carrier and the Physician."

Nicholas Murray Butler, president of the university

Dr Northrup, who, as winner of the award, will deliver the annual Chandler lecture next spring, was cited for fundamental discoveries concerning bacteria, the constitution of protein, and the chemistry of digestion

Niagara County

DR CLYDE W GEORGE, assistant superintendent of the Niagara Sanatorium, was elected president of the Niagara County Medical society at a meeting on Dec 8 Dr George has been secretary for the past two years

Dr Nicholas I Ardan, was chosen vice-president, Dr Forrest W Barry, secretary-treasurer and Dr R R B FitzGerald, a member of the board of censors

Dr Floyd S Winslow, president of the State society, speaking after the business meeting, said that the American Medical association is convinced that the present system of medical practice remains the best.

Dr Winslow explained that although twelve states have declared for a basic science law for qualifying doctors, the New York State association is opposed to it "because it would legalize practice of medicine by chiropractors"

Oneida County

DR M T POWERS is slated for election as president of the Utica Academy of Medicine to succeed Dr T Wood Clarke

He was nominated Dec 17 at the largest meeting ever held by the academy, more than one hundred physicians and surgeons attending

Dr Temple Fay of Philadelphia, one of the outstanding neurosurgeons of the country, presented a paper on "Spinal Drainage, Its Role in Cerebral Problems," and so many questions were asked that he spoke till after midnight.

Dr F M Miller Sr chairman of the nominating committee, presented this slate for the election Jan 21 President, Dr M T Powers, vice-president, Dr William W Wright, secretary, Dr F M Miller Jr, treasurer, Dr H D Parkhurst, trustees, Dr Fred E Sabin, Dr Rose D Helmer, and Dr R C Borst Three trustees hold over, Dr J L Golly, Dr John F Kelly and Dr F M Miller Sr

Dr Wiliam C Jensen, read a paper on "Lung Abscess and Bronchiectasis Secondary to Pulmonary Carcinoma"

Onondaga County

DR JAMES K QUIGLEY, chief obstetrician

of General Hospital, spoke before the final meeting of the obstetrics symposium of Onondaga County physicians Dec. 10 in St. Joseph's Hospital, Syracuse. Doctor Quigley, chairman of the maternal welfare committees of New York State Medical Society and Monroe County Medical Society, spoke on "Normal Labor"

Ontario County

"MENTAL ASPECTS OF THE AVERAGE PATIENT" was the subject of a paper by Dr Robert M Ross, of Brigham Hall, on Dec 10 at a meeting of Canandaigua Medical Society Dr Frederick C McClellan was host at dinner preceding the business session and program Dr A M Mead, was host for the annual meeting Jan 14 when Dr J F McAmmond gave the president's address

Orange County

DR J EMERSON NOLL was elected president of the Orange County Medical Society at the annual meeting in Middletown, on Dec. 8

Other officers elected were vicepresident, Dr Harry Pohlman, and secretary Dr E C Waterbury The Board of Censors includes Dr Daniel I O'Leary, Dr Walter Hursemann, Dr J Morrison and Dr Russell Schmitt

Dr George V Carneal, instructor of surgery at Columbia University, spoke on "Treatment of Varicose Veins and Ulcers."

Rensselaer County

DR STEPHEN H CURTIS was elected president of the Rensselaer County Medical Society at the Society's annual meeting Dec 8 Other officers chosen were Vice president, Dr Hugh V Foley, treasurer, Dr John F Russell, re-elected, secretary Dr Leo S Weinstein, re-elected, censors, Dr William M Trotter and Dr Charles W Hamm, delegates, Dr John D Carroll and Dr W B D VanAuken, and alternates, Dr George D Hoffeld and Dr G Elmer Martin

The new officers assumed their duties at the annual dinner the next evening, in the Hendrick Hudson hotel in Troy An illustrated lecture on "The Relief of High Blood Pressure Through Surgical Treatment," was given by Dr George W Crile, of Cleveland, Ohio

Richmond County

THE RICHMOND COUNTY MEDICAL Society renamed its entire staff of officers, delegates and committees at a meeting on Dec. 9

hospitals will be the only institutions in which nurses can receive their training. Whether such training is apprentice training, as much of it must be, or academic, as some of it will be, the hospital remains the laboratory and school for the nurse.

The purpose of the hospitals in training nurses is primarily for the care of the sick either in the hospital or the home. Ninety-five per cent of the cost of such training comes from the revenues of the hospitals, a very large portion of which is provided by the patient who pays for his hospital care. With the lengthening program for the education of the nurse, together with the added instructional facilities to educate and prepare the nurse for specialized fields, the hospitals are finding it increasingly difficult to operate their training schools. Many are employing graduate nurses for supervisory services and, because they cannot secure graduates for floor duty and other services, are adding maids to do the menial part of the work and glorifying them by calling them nurse aides.

In the past one of the main compensations the hospital received from operating its training school was the assurance of having a constant supply of its own graduates to staff its nursing service. In recent years this compensation seems to be denied, for out of the 18,500 nurses who are graduated each year less than one-fourth of that number enter institutional work.

The hospitals have been and still are the largest employers of graduate nurses. In the depression period 60,000 nurses were constantly employed in our institutions. In normal times this number is increased to 70,000.

There is approximately a constant of

160,000 graduate nurses available for employment. Five years ago 5000 of this number were employed as public welfare nurses today 20,000 are so employed and if reports are correct 50,000 are needed. The question immediately presents itself, "Just how much is the responsibility of the hospital to train the public welfare nurse in her particular specialty?" Twenty thousand more graduate nurses are employed in physicians' offices, 20,000 in industrial plants and commercial houses, 4000 as nurse anesthetists and probably 6000 more in activities not listed above, a total (including the 60,000 employed by hospitals) of 110,000, leaving but 50,000 nurses to care for the sick in homes throughout the country.

The maid in the hospital who is intelligent and who becomes the nurses' aide will, after a year or two, begin to seek employment in the homes of the sick as a practical nurse, and many will be employed. One hundred thousand practical nurses are being so employed at present. The training of nurse aides will inevitably increase the number of practical nurses, who will compete for employment with the graduate nurse.

Hospitals want nurses trained properly. They want the intelligent student in training and the competent graduate to serve their patients. They will go just as far in developing the program for the education of the nurse as their financial resources will permit. They must have well-trained, qualified graduates for their nursing service. It is very doubtful whether it is the function of the hospital, certainly it is not the responsibility, to educate the nurse for service in highly specialized fields of nursing.

American "Hospital"-ity

HOSPITAL AND HOSPITALITY both derive, of course, from the same Old French root, going back to the Low Latin "hospes," a guest. So when Sir Lenthal Cheatele tells of his experience as a guest of our hospital authorities in this country, the *London Times* appropriately captions his letter "American Hospitality." Sir Lenthal writes

"Will you allow me to give you an example of the hospitality I received when I

was lately in America?

"The Hine Hospital of Chicago is a famous Government institution, to the staff of which only American citizens are appointed. To make it possible for me to lecture there the American Government made me a temporary consulting surgeon, and for a week made me an American citizen.

"May I take this opportunity of expressing my pride and gratitude for this unique honour?"

Hospital News

"Optimism for 1937"

THAT WAS THE NOTE SOUNDED in his inaugural address by Dr C W Munger, of Grasslands Hospital, when he became President of the American Hospital Association at Cleveland at its annual convention. In sounding this "note of optimism for 1937" in the hospital world, Dr Munger declared, as his address is "digested" in the *Westchester Medical Bulletin* "We who have lived through the depression cannot ever forget it, but in recent months I have found unmistakable signs of improvement in the hospital situation. Occupancy figures are climbing, almost without exception, municipalities are coming nearer to paying cost for care of the indigent, semi-private and private rooms are being reoccupied, and business is far above the level of a few years ago."

Dr Munger suggested, nevertheless that hospital management "take stock, now, of the quality of the work our hospitals are doing, and be ready, no long time hence, to come out of the red both in grade of service and in finance."

Turning to the much debated subject of anesthesia in hospitals, Dr Munger pointed out that while the A. H. A. should continue to maintain "an impartial attitude" toward the question of nurse-versus physician-anesthetist, nevertheless "with the advent of spinal intravenous and other routes for the introduction of anesthetic agents, the plot has thickened, and these newer methods will bring the physician into a progressively more prominent position in the field of hospital anesthesia."

"It is time," he said, "for every hospital to take stock of the efficiency and safety of its anesthetic work,"—and recommended consideration of the plan of a combined department embracing anesthesia, resuscitation, prolonged artificial respiration, oxygen therapy, and other gas therapies, as suggested by Dr P J Flagg and the Society of the Prevention of Asphyxial Death.

Dr Munger also spoke of the need of overhauling the hospital residency program to keep pace with "the rapid development of Examining Boards and standards for the specialist's preparation by all of the principal medical specialties",—the importance of hospital publicity, "for the purpose of stimulating the support of hospitals by donations from the public",—and urged, also that more attention be given to "the encouragement of real hospital social service work, quite aside from the function of financial investigation."

"Last," he said, "let me mention the importance of continuance of the best possible cooperation with the American Medical Association, American College of Surgeons, Public Health Association, and similar groups within the medical profession. With out them, we are helpless. They are rapidly realizing how important we are to their aims."

Dr Munger's well-deserved recognition by the hospital association, says his home-county *Bulletin* in conclusion, is a source of great satisfaction to his colleagues and associates throughout the County.

The Disturbing Scarcity of Nurses

HOSPITALS IN MANY PARTS of the country have been having difficulty of late in securing enough competent registered nurses for floor and supervisory duty. Fewer training schools, longer training courses, the decrease in the number of graduates from a peak of 24,000 annually to 18,500 at present, and the reduction in salaries, together

with the greatly increased employment of nurses in positions remotely connected with the bedside care of the patient are the contributing factors to the situation that is becoming increasingly difficult, according to a thoughtful editorial which appeared recently in *Hospitals*.

In the past, as well as for the future,

237 agencies occupied with public health nursing," Dr Rappelye said "There are between 140 and 160 general hospitals. These hospitals give treatments totaling 12,000,000 patient days at a cost of about \$5 a day, or \$60,000,000 a year. Probably five per cent of the people treated could be cared for adequately by home service at a cost of \$1 to \$1.20 a day.

"The city needs about 2,000 more public health nurses and a co-ordination of their activities with the hospitals. The community is going to be increasingly responsible for community health."

DR JOHN L. RICE, City Health Commissioner, speaking at the recent twenty-fifth anniversary dinner of the Lutheran Hospital of Manhattan, urged hospitals to take greater interest in preventive education and in the treatment of diseases in the early stages. The dinner, held at the Hotel Astor, was attended by 500 persons.

"New York City's birth rate is falling, so we must take better care of the babies we have," Dr Rice said. "There is no better place than the hospital where the baby is born to impress the parents with the importance of immunization against diphtheria. Each year about 1,000 die from appendicitis—we must do better there."

"The maternity picture is not very good in New York. Too many mothers are dying, and there must be improvement there. It seems to me the hospitals are missing one of their biggest opportunities for public service in not stressing preventive medicine more."

Both Dr Rice and Dr S. S. Goldwater, Commissioner of Hospitals, praised the hospital, located at 343 Convent Avenue,

for its fine record and growth. Dr Goldwater remarked that the hospital had started chiefly to give service in the home, a service to which other hospitals are now turning.

THE NEW CANCER CLINIC at the White Plains Hospital was officially opened October 9. This clinic, equipped with the most modern deep therapy apparatus was made possible by the generous gift of an anonymous donor, according to an announcement by Mr. John W. Appel, President of the Hospital. The cancer service at White Plains Hospital is carried on in direct co-operation with the Memorial Hospital of New York City. To further this relationship, Dr. Fred W. Stewart has been appointed consulting pathologist and Dr. Hayes E. Martin, consulting surgeon, both of whom are on the staff of Memorial Hospital. Dr. Alfred T. Hocker, a former member of the Memorial Staff has been appointed associate radiologist. Dr. R. D. Duckworth will serve as attending radiologist. The new apparatus, a 200 K. V. machine is placed in a room entirely sheathed in lead sheets.

THE BOARD OF GOVERNORS of the New Rochelle Hospital has recently announced the election of Mr. Albert L. Viles of New Rochelle as its new President, succeeding Mr. Ralph S. Kent who resigned the Presidency of New Rochelle Hospital after ten years of service. Mr. Viles, President of the Rubber Association of New York City has had a long and successful experience in hospital work, but he will have a very difficult task to equal the outstanding achievements that have marked Mr. Kent's Presidency.

NEW INDUSTRIAL HYGIENE LAB

The Laboratory of Industrial Hygiene has been incorporated under the laws of the State of New York as a nonprofit organization empowered to carry on scientific and industrial work in chemical, bacteriological, and, in general, public health problems, to accept grants for definite scientific purposes, etc. Its officers include Dr. William Hallock Park, President, Miss Grace McGuire, M. A., Secretary, and Dr. K. George Falk, Vice-president and Treasurer. Its staff includes Miss Grace McGuire, in charge of

chemical work, Mrs. Eugenia Valentine Colwell in charge of bacteriological work, Dr. K. George Falk, Director, Dr. William Hallock Park, Consultant, and a number of assistants.

The laboratory includes at the present time the following units: (1) Certified Milk Laboratory under the direct supervision of Dr. Park, (2) Vitamin Testing Laboratory, (3) Clinical Diagnostic Laboratory, (4) Chemical Laboratory and (5) Bacteriological Laboratory.

Hospital Notes

DR. JOSEPH JACOBSON, of Kingston, was unanimously chosen by the Board of Supervisors in December to be a member of the Board of Managers of the Ulster County Tuberculosis Hospital.

DR. WILLIAM E. MORRIS, thirty-six, chief Roentgenologist at Grasslands Hospital, Eastview, died there Dec. 10 from an abscess of the brain. He had been ill for three days.

He was born in Decatur, Texas, and attended the University of Texas. After serving in the U. S. Navy during the World War, Dr. Morris practiced privately, and in 1929 joined the staff at Grasslands. In 1933 he was appointed head of the x-ray department at Grasslands and recently took over similar duties at the Northern Westchester Hospital in Mount Kisco.

Dr. Morris was a member of the American College of Radiology and had conducted research in deep therapy for the treatment of cancer.

He is survived by his widow, Dr. Joyce Springer Morris. They lived in Mount Kisco.

A BRONZE BUST of the late Dr. William Francis Honan, for forty years Professor of Surgery at the New York Medical College and Flower Hospital, was presented to the trustees of the college Dec. 15 by the senior class at a ceremony in the senior lecture room of the college, 450 East Sixty-fourth Street. The bust is the work of Leonard Rubin, a senior medical student. Dr. Honan died a year ago.

Charles B. Tramont made the presentation. Charles D. Halsey, president of the board of trustees, in a brief acceptance speech praised Dr. Honan as "a man wholeheartedly devoted to the greatest heritage of medicine." Brief talks on the life and career of Dr. Honan were made by Dr. Arthur R. Grant, Dr. Samuel B. Moore and the Rev. Edmund M. Wylie.

SOMEBODY SUGGESTED IN PARIS recently that the surplus unsold garden produce thrown away every day at the central markets be given to the hospitals, but the market gardeners objected, made demonstrations, started riots. The truck gardeners agree that if hospitals and institutions think

they have any chance of getting their vegetables free, they will no longer buy any. This means that prices are depressed and sales are increased. They say there is no reason why they should be obliged to furnish free food for charitable purposes.

ANYONE IN NORTH BRAZIL injured in an accident in a Ford car will receive free medical and surgical attention at the new hospital in Rio de Janeiro being built by the University of the Federal Capital. The university is seeking permission to name the hospital "Henry Ford," in recognition of the manufacturer's contribution toward development, economic improvement, sanitation, and general welfare in the northern part of Brazil.

ACCORDING TO THE American Hospital Association only twenty-five per cent of all hospitals throughout the United States having a bed capacity of 200 or more have a dental service. Approximately 250 hospitals have a well defined dental service. Of the patients in wards, ninety-five per cent are in need of dental attention.

A COMBINATION COLLEGE and vocational school has grown up at Butler Hospital, an institution for the care of the mentally ill, at Providence, R. I. Instruction is offered in almost any subject desired, if it will build up confidence and ability in the patient, for the hospital recognizes the principle that learning should never cease.

DR. WILLARD COLE RAPPLEYE, dean of the College of Physicians and Surgeons of Columbia University, said a few weeks ago in an address on the need for coordinating public health nursing and hospitalization that home treatment of some of the patients now treated at the general hospitals would save the city approximately \$2,400,000 a year.

Dr. Rappleye spoke at the home of Mrs. John V. Bouvier 3d, 740 Park Avenue, at a meeting of the New York City silver jubilee committee of the National Organization for Public Health Nursing. Plans were made for the celebration of the twenty-fifth anniversary of the national organization.

"A recent survey in New York City shows

of silver nitrate solution and neo silval Part of his testimony on cross-examination was as follows

Q When you start out with the treatment, it is proper to use an astringent and wash to reduce the inflammation and swelling?

A Yes, sir

Q And use boric acid as a washing solution?

A Yes, sir

Q When you start in to treat the germ itself, the use of neo silval would be proper? A. It is used by a good many

Q It is a recognized, standard, proper treatment, is it not? A. Well, it is used

Q You would not say its use was improper in any way, shape or form? A No, sir

Q You would not say that any person using that was not using the proper ingredient? A. It might be used

Q Now doctor, you made the statement on the stand with respect to the nature of the disease that existed with respect to this eye, if I understood it correctly, it was that regardless of the treatment that might be given to a person, it would be perfectly possible to lose the sight of the eye if he had the disease in question? A. Yes, sir

At the close of the plaintiff's evidence the Trial Court granted judgment in favor of the defendant, and from that judgment the plaintiff appealed

The Appellate Court determined that the ruling in favor of the defendant had been proper, and affirmed the judgment. In so ruling the Court stated the reasons for its decision as follows

After a careful study of the several briefs filed by counsel for plaintiff, we have concluded that they rely upon the following omissions to establish the negligence of defendant (1) Failure to cap plaintiff's right eye, (2) failure to take a smear from the left eye and have it tested, (3) failure to hospitalize plaintiff, (4) failure to use more energetic treatment on the eye. We will consider the several specifications in the order stated.

If we assume, without holding, that good practice required the defendant to cap plaintiff's right eye, the failure to do so furnishes no ground for a reversal of the judgment. That eye was not infected and was not injured in any way. The failure to cap it was neither a proximate nor a contributing cause of any injury suffered by plaintiff

Dr M was of the opinion that good practice required defendant to take a smear from the infected eye. It is admitted that one was not taken. According to this witness, the purposes of the smear and its examination are (1) to determine the nature of the infection, and (2) the nature of the treatment, the nature of the treatment being dependent on the nature of the infection and its virulency. Defendant recognized the nature of the infection at his first examination and Dr M admitted that this could be done. Therefore, the only merit in this contention would depend upon the pro-

priety and efficacy of the treatment administered by defendant which must be considered under the last ground urged for reversal

There is no evidence to support the argument that hospitalization was a necessary part of the treatment of the disease required by the standards of good practice of an eye specialist in and around E. The testimony of Dr M on this question, which we have quoted does not support any such conclusion. The only conclusion to be drawn from his evidence is that hospitalization is desirable and that the doctor himself did not see how a patient could properly irrigate his own infected eye. This falls far short of establishing that the standard treatment in E. required hospitalization of patients suffering from gonorrheal ophthalmia

When we analyze the evidence of Dr M on the question of the propriety of the treatment administered by the defendant, we find that his ultimate conclusion was contained in his statement that, "If I were treating such a case, I would want to have more energetic treatment. In this serious disease the outcome might be grave in any event." He testified that "there is a great difference in the opinion about the use of drugs" He specially said that each step in the treatment administered by defendant was proper. This did not establish that defendant did not bring to the case, and did not use in his treatment of plaintiff "that degree of skill and knowledge which is ordinarily possessed by those who devote special study and attention to that particular organ, injury or disease, its diagnosis and its treatment, in the same general locality, having regard to the state of scientific knowledge at the time." It only tended to prove that in the opinion of Dr M a method or mode of treatment, or measures used, other than those employed by defendant, might have had a better result. This is not sufficient to make out a case for plaintiff

Extraction of Teeth

A woman about forty years of age consulted a general practitioner, who conducted his practice in a rural community, with respect to various complaints. From time to time in the course of the treatment he rendered her he extracted six teeth and so far as the removal of certain teeth were concerned there were no complications

An action was instituted against the doctor on behalf of the patient in which the charge was made that three of the teeth extracted by the defendant were sound and that at the time he removed the teeth he was under the influence of intoxicating liquor. It was further claimed that the teeth were negligently removed so that plaintiff's jaw had become swollen and inflamed and the plaintiff developed a condition of neuritis. Subsequent to the time of the treatment, and prior to the commencement of the action,

LORENZ J. BROSNAN, ESQ

Counsel Medical Society of the State of New York

Malpractice—Liability of Eye Specialist

A case passed upon very recently in one of the Pacific Coast States* presents an interesting situation in which a patient attempting to hold a physician responsible for the loss of an eye, failed to do so because it was impossible for him to produce sufficient evidence to establish that the doctor's handling of the case did not measure up to the proper standard of care.

The defendant in the action had engaged for twenty-five years in the practice of medicine as an eye, ear, nose, and throat specialist. Upon the trial he was called by the plaintiff as a witness to give his version of the facts. It seems that on May 22, 1933, the plaintiff came to him with a badly swollen and infected left eye. According to the defendant he examined the eye and diagnosed the condition as gonorrheal ophthalmia. Treatment that day consisted of irrigating and cleaning the eye, and painting the lids with one per cent silver nitrate solution. He told the patient of the danger of the condition. He advised continuous ice applications, and cleansing with salt or boric acid solutions. Also it seems that atropine solution was instilled in the eye, and the patient was given a prescription for a zinc sulphate solution with instructions for use every two hours. According to the defendant, on the next day in place of the latter solution he directed the use of a fifteen to twenty per cent solution of neo silval. The patient returned daily to the doctor for treatments until June 1, receiving similar treatments at each visit. On May 31 the defendant doctor diagnosed the presence of a corneal ulcer and painted the eye with a mercurochrome solution. The defendant did not take a laboratory test of any smear, for, as he testified, he was convinced throughout that he knew the nature of the infection. He did not order hospitalization, for the reason, he said, that plaintiff could not pay the expenses, and there was no free hospital available.

The plaintiff described the history of the treatment received and in most respects did not differ from the version of the doctor, outlined above. He did claim, however, that his right eye was never capped by de-

fendant and that he was not advised to enter a hospital although he had enough funds to take care of hospitalization if necessary. He testified that before he had consulted the defendant his eye had been painful for two days, and that he had used some argyrol as an eye lotion. He described the presence of pus in his eye when he first visited the defendant. The patient differed somewhat as to the date the use of neo silval was begun, but described having faithfully carried out all instructions. He told of daily visits to the defendant until June 1, and testified that on that day the doctor had told him "I am afraid your eye won't do you any good any more."

The following day the plaintiff went to another eye specialist in a neighboring city, a Dr. M., who removed the eye-ball on June 2.

Upon the trial the plaintiff called as a witness the said Dr. M. who stated that when he first attended the plaintiff the eye was in bad condition, full of pus, with a perforated cornea and a prolapsed iris. He took a smear, and a laboratory test showed that the infection was gonorrheal. According to Dr. M. at that time sight was destroyed beyond hope of restoration and for that reason the operation was performed. Hospitalization of a week was required, and some weeks of treatment were necessary to cure the infection in the socket. Dr. M. gave considerable testimony as an expert witness which indicated that his treatment would have been different, and that he did not approve the course of treatment pursued by the defendant. Upon the subject of the need for hospitalization he said "I believe that every man would preferably like to have his patient in a hospital for the treatment of this disease no matter where he is. Sometimes we cannot always put our patients where we want them. I do not see how any individual can take care of their own eye with this disease."

However, upon cross-examination the value of Dr. M.'s testimony for the purpose of establishing the plaintiff's case was lost. He testified that ice was a recognized treatment, that zinc sulphate could be used as an astringent, and that boric acid was a proper irrigation. He also endorsed the use

Across the Desk

Buffalo Doctors Have "Started Something"

A LITTLE SCENE AT three in the morning last winter, when the mercury was hiding down below the zero mark and the swirling snow was two feet deep in the streets of Buffalo, "started something" of enormous benefit to that city and of equal good to any other town that has the enterprise to follow a good example when it sees it. Two persons were battling through the drifts on that wintry morn, as the Buffalo papers are now telling the story

One was a doctor and the other a messenger boy. After ploughing through snow over their knees for almost a half hour trying to find the houses where they were to go, they gave up and retreated to the doctor's car to get warm before beginning the search all over.

In the car they swapped experiences about the difficulty of finding houses which either had no street numbers or ones which could not be read. They agreed something should be done about it. Something has been done.

Dr James L. Gallagher, 696 Broadway, chairman of the legislation committee of the Erie County Medical Society, was the doctor marooned on the street without house numbers. He took his complaint to the medical society and received unanimous support in starting a drive. The result is that thousands of homes and buildings in Buffalo were posted with four-inch house numbers, which will enable anyone to find them on a street with the least possible effort.

According to an estimate made by G. R. Clifford, a department manager for Weed & Co., at least 140,000 new house numbers were sold in Buffalo, just before the ordinance went into effect the latter part of last month.

The success of the campaign which really had its start on a cold morning last winter has startled pleasantly Dr Gallagher and the Erie County Medical Society which sponsored it.

Inquiries about how to start a similar drive have come to the county association from doctors in all parts of the state and *Medical Economics*, a national medical magazine, is urging physicians all over the country to follow the Buffalo plan.

"We are delighted with the response to our appeal," said Dr Gallagher. "There are at least 100 physicians on night calls about the city and many of them have reported to the society that they consider the new house numbering something of a blessing. We do not

think it worked hardship on anybody for the numbers cost only a trifle. But the benefits to physicians in time saving is enormous."

Besides the doctors' favorable comment on the new legible letters, taxi drivers, postmen new on routes, delivery men and clergymen have written letters to the medical association officers thanking them for starting the campaign.

The doctors are delighted, but they feel there is still some room for improvement.

"To make it perfect for night travel about the city something should be done to make it possible to read signs on street corners at night," said Dr Gallagher. "We feel that some of the WPA expenditures in Buffalo are to be commended in that they will benefit the citizens. The Roesch Stadium for instance will benefit Buffalonians several times in the year."

"The cost of just a corner of the stadium would buy reflectors to throw the street light back on the name plates. This would benefit the entire population of Buffalo and all its visitors 365 nights in the year," said Dr Gallagher.

The campaign to have every house and building in the city numbered with easily read letters is to continue. Houseowners who do not comply will be summoned to court. A maximum fine of \$25 may be imposed.

Dr Gallagher Tells the Story

We are fortunate enough to have a letter from Dr Gallagher himself, telling about the house-number campaign. He writes as follows to the Secretary of the Journal Management Committee

November 21, 1936

Peter Irving, M.D.
New York State Journal of Medicine,
33 W 42nd Street
New York City, N Y

My dear Dr Irving

I promised you the story of the Erie County Medical Society's campaign for legible numbers on all of Buffalo's buildings.

I believe that it will be of interest to all physicians, and of special interest to up state New York physicians, for I see about the same conditions as to house numbering in most of the up state cities and towns, that confronted us—and that was that it was nobody's business—and no one did anything about it.

The situation was that a number of some kind was placed on a house when it was built, if the owner happened to think it was necessary. It varied in size from one to three inches high,

the plaintiff had removed to a village approximately two hundred miles from the place where the defendant was engaged in the practice of his profession. The venue of the action which was instituted against the defendant was the County to which the plaintiff had removed. A motion was made on behalf of the defendant for an order changing the place of trial to the County where the defendant resided, particularly on the grounds of convenience of witnesses. The Court granted the said application. Thereafter the plaintiff's attorney never indicated any desire to bring the case on for trial but from time to time tried to bring about a settlement of the action. No offer of settlement was made on behalf of the defendant and the matter was finally terminated by a discontinuance of the action.

Broken Needle in Leg

A doctor engaged in general surgery was called to the hospital to attend a middle-aged man whose leg had been injured when a limb from a tree had fallen on him. X-rays were taken and it was ascertained that there was a comminuted fracture of the right tibia with a considerable amount of swelling and bruising and with the leg bowed outward. The doctor determined that an open operation was necessary to reduce the fracture. The following day the operation was performed and the bones were held into position with two separate wires. In inserting one of the wires the tip of a curved needle broke off but the point could not be recovered. The doctor decided against probing for it feeling that to do so would cause unnecessary trauma. A plaster

cast was applied which was permitted to remain on the leg for six weeks. It was found necessary at the end of that time to make an incision and replace one of the wires which had become loosened. A second cast was applied which was permitted to remain on the leg for a further period of time. About three months after the original injury under a local anesthesia the doctor took out the wires. The final result was that the patient had a good functional leg with no deformity in the foot, ankle or knee. The broken tip of the needle, however, remained imbedded in the leg. At the end of a reasonable length of time the patient was able to walk normally without a cane and to drive his car.

A malpractice action was brought against the surgeon in which the charge was made that he had been negligent in permitting the needle to break and the plaintiff claimed that as a result of said negligence it was necessary for him to undergo two subsequent operations for the purpose of having the needle removed.

The action came on for trial before a Court and Jury and it was established that the two subsequent operations were in fact performed by some other physician. The defendant in his testimony admitted that the needle broke. He also testified that the breaking of the needle was caused by no negligence on his part and that in his best judgment it was advisable to permit the needle to remain within the leg as he felt it would do no harm.

At the close of all the testimony, on motion of the attorney for the defendant the complaint was dismissed, the Court thereby exonerating defendant of all charges of malpractice.

NATIONAL SOCIAL HYGIENE DAY

Plans for the first National Social Hygiene Day, to be held February 3, are announced by the American Social Hygiene Association, of 50 West Fiftieth Street, New York City. On this day, state and community voluntary organizations interested in the control of syphilis and gonorrhea and other social hygiene problems, with the advice and approval of health authorities and the medical and allied professions, are planning to hold meetings all over the United States.

In New York City, the American Social Hygiene Association will hold its annual meeting on February third. Also the Social Hygiene Council of Greater New York will hold its Fifth Annual Regional Conference

at the Hotel Pennsylvania on the same day. It is expected that public leaders, including Surgeon General Parran, President Ray Lyman Wilbur of Stanford University, President of the American Social Hygiene Association and former Secretary of the Interior, will speak to these meetings. National agencies and many of their state and community organizations which include social hygiene activities in their yearly programs are planning to participate. It is probable that a nation-wide radio hook up will provide addresses of great importance from high government officials and civic leaders in different parts of the country as a climax to the activities of the First National Social Hygiene Day.

And Here is the Ordinance

In order to aid medical societies which plan similar campaigns in their own cities, it may be useful to quote Buffalo's ordinance, which resulted in making its streets easier to explore. It reads

It shall be the duty of every owner of a building in the City of Buffalo to cause to be displayed thereon the street number of said building, and at all times to maintain such number in compliance with the provision of this chapter (Section 1 of Chapter XXVII)

The figure or figures comprising said number shall be at least four inches in height and shall be placed on said building in such a

manner as to be legible plainly from the center of said street at all times between sunrise and sunset. The color of said figures shall be in sharp contrast to the color of their background. Such numbers shall be placed on the top riser of the steps leading to the front entrance of said building, or other permanent place on the front of the building

Any person, firm or corporation who violates any provision of this section shall be liable to a fine or penalty of not to exceed \$25

"Top riser" in the ordinance was opposed by the medical society because the number might be obscured by snow, but was inserted by the Corporation Counsel's office, which drew the ordinance

MEDICAL RELIEF TO SPANISH CIVIL WAR VICTIMS

An urgent humanitarian appeal for medical aid to the victims of Spain's Civil War has been addressed to physicians of this country by a national committee of eminent American members of the profession. This committee is sponsoring the work of the Medical Bureau of the American Friends of Spanish Democracy, 20 Vesey Street, New York City. The Medical Bureau is now organizing an American ambulance corps and a fifty-bed surgical hospital, the first unit of which is expected to leave this country within the next few weeks. A sanitation corps and a base hospital for civilians evacuated from Madrid is also planned.

Urging that the medical profession cooperate in this relief project, Walter B Cannon, professor of physiology, Harvard University Medical School, in a telegram to the Medical Bureau stated, "Anyone knowing the torments of war victims even under the most favorable conditions can imagine how pain and anguish are intensified by need and neglect. I sincerely trust that aid may be given to the suffering defenders of Spanish Democracy."

The Medical Bureau was created in this country in response to the Spanish Loyalists' Government plea for diphtheria toxoid to prevent a threatened epidemic among the children of Madrid following one of the early air raids. Since then the civilian population has been subjected to more harrowing experiences than the population of any other modern capital. With the destruction of hundreds of homes, thousands of refugees have been threatened with various epidemics.

Four specially constructed ambulances

have already been purchased with funds donated by American citizens. These, together with the fifty-bed surgical hospital staffed by American physicians, surgeons and nurses, will comprise the first unit. They are expected to leave for Spain within a month. The personnel is now being chosen from more than 120 volunteers by a special examining board of physicians and surgeons.

The national sponsoring committee includes the following prominent members of the profession: Drs Thomas Addis, Leland Stanford University Medical School, George Baehr, Ernst Boas, E M Bluestone, New York City, Walter B Cannon, Harvard University Medical School, Haven Emerson, Columbia University Medical School, Frederic A Gibbs, Harvard University Medical School, Samuel J Kopetzky, New York City, Samuel A Levine, Peter Bent Brigham Hospital, Boston, John P Peters, Yale University Medical School, William H Park, New York City, Henry E Sigerist, Johns Hopkins University, Institute of the History of Medicine.

Local committees for each borough have been organized and a special city-wide committee of physicians is now being created to handle the drive in New York City. Physicians who desire to aid are urged to communicate with the headquarters of the Medical Bureau at 20 Vesey Street, telephone Barclay 7-3811 or 3812. Money is needed to complete the equipment of the surgical hospital. Contributions are urgently solicited. Supplies such as diphtheria toxoid, typhoid vaccine, insulin, bandages and surgical instruments, transfusion sets, and sterilization equipment are also needed.

WITH THE PROBLEM OF POOR HOUSE-NUMBERS CONQUERED, THE NEXT OBJECTIVE IS IMPROVED STREET SIGNS

was placed wherever the owner happened to place it, and then forgotten. It was painted over when the house was painted, and if it fell off, it was not replaced.

The result was thousands of homes without a number of any kind, thousands more where it could not be found at night, and even at best, it was a go as you please affair, and never thought of by the owner or tenants

It was a real hardship for physicians and still worse for patients, for much valuable time was lost by both. Many tragedies have resulted from this loss of time spent while doctors were searching for numbers.

Our committee on Legislation put our society on record as requesting that something be done about this, first in the interest of the sick, and secondly—for the benefit of physicians—and the score of other classes of citizens whose occupation made it necessary to find numbers.

It came as a complete surprise to our society who had suffered so long but did not think of trying to correct it.

It came also as a complete surprise to the members of our Common Council who had not thought of its seriousness until it was pointed out to them—and when it was, I wish to say to their everlasting credit—every last one of them voted for it—the Mayor signed the ordinance—the Police commissioner saw to its enforcement and in ninety days, we had a city of six hundred thousand people with most of its ninety thousand homes displaying a four inch number—that can be seen day or night—from the center of the street.

And what a paradise it is for a doctor to drive along any street now—and read the house numbers from his automobile.

The numbers have cost from five to ten cents each. Anyone can manufacture them—anyone can sell them—so there is no question or possibility of monopoly or graft.

The plan called for a great deal of publicity of course, but we could not have put it over by our method without the help of the daily press.

Without the help of the press we would have been obliged to ask for a large appropriation—and an army of workers, and even if we got it—it would have taken two or three years to cover the city and would have cost the taxpayer one hundred times in taxes what it cost them to buy their own numbers.

I believe every doctor in the state would be interested in our story—and I think the Journal would be rendering our profession a great service in giving this little information as to how doctors might proceed to change conditions in their own cities and towns.

I am enclosing a few of the newspaper clippings—that will help you to summarize our plan—and our method of bringing it before the public.

Necessarily, as chairman of our committee on Legislation, I had to accept a great deal of unwanted publicity, but our members knew that someone had to accept it under our plan of promoting it, and they are very grateful to the newspapers who helped us so much, and to the Legislative Committee for what has been accomplished, and to the general public for their wonderful response to our appeal.

Yours very truly,

JAS L GALLAGHER, M.D

act and abridged form his ideas and views obtained in his encyclopedic work "Studies in the Psychology of Sex" in 7 volumes. For sheer erudition Ellis has no superior. The book begins with a consideration of the biological foundation of sex. He discusses the role various sensations play in the stages preparatory to the sexual act. Masturbation is treated as a broad biologic fact with sympathy and understanding. In the chapter on sexual deviations he discusses homosexuality, fetishism and various other abnormalities of sex, which he considers as symbolic representations of the sexual urge. Although he gives credit to Freud for his contributions to sexology, he does not entirely agree with his views. There is an abundance of sound advice to those who by virtue of sex frustration or other hindrances have developed neurotic symptoms. It is unnecessary for the reviewer to go into detail about the merits of this book. Suffice it to say that it represents the labor of a lifetime by a master in his chosen field. It is a book for all intelligent readers who wish to obtain a comprehensive and clear view of many of the sexual problems which may confront them.

JOSEPH SMITH

Williams Obstetrics A Textbook for the Use of Students and Practitioners By Henry J. Stander, M.D. Seventh edition. Octavo of 1269 pages, illustrated. New York, D. Appleton Century Company, 1936. Cloth, \$10.00.

Williams' Obstetrics has been accepted as an outstanding work on the subject, not alone for the student and practitioner, but as a reference work as well. For any man to undertake a new edition meant accepting a task that might impair the value of the book, as well as his own reputation. It was quite natural that this task should be undertaken by Stander, for many years a close associate of Williams and one of his outstanding disciples. The result is one of the finest treatises on obstetrics that it has been the reviewer's privilege to read.

The chapter on Maturation, Fertilization and Development of the Ovum is unusually excellent, the chapter on Hormones is well written and easily understandable.

The chapter on Anesthesia, Analgesia and Anesthesia is a fine evaluation of all methods, past and present, employed in obstetrics and should be reprinted in some of our popular magazines to correct the impressions produced by articles published by some of our so-called obstetricians and pharmaceutical houses.

The chapter devoted to Multiple Pregnancy is clear, concise and up to date. That on toxemia is an excellent exposition of the

knowledge at hand. Stander, like all other writers, discourses volubly against radical treatment (and we subscribe to this) advocating conservative treatment until fully dilated, then forceps or version. What the reviewer would like to know (and there are many like him) is this: what is his treatment of the woman who, in her first pregnancy, reaches the stage of 35 or more weeks of pregnancy, has a big baby, an uneffaced rigid cervix and is eclamptic? A satisfactory answer to this question is still eagerly awaited by the multitude of obstetricians.

We would rather he had said less about manual dilatation and more about Dührssen Incisions. As for Vaginal Cesarean Section we feel that it cannot be recommended after the period of viability.

Deformity of the pelvis is treated most thoroughly and a really satisfactory definition of "test of Labor" is set down. The discussion of induction of premature labor in disproportion is one that the few remaining induction enthusiasts should read carefully.

The management of placenta previa as outlined by Stander conforms to the views as persistently advocated by the reviewer.

JOSHUA RONSHEIM

A Textbook of Pathology By W. G. MacCallum. Sixth edition, entirely reset. Octavo of 1277 pages, illustrated. Philadelphia, W. B. Saunders Company, 1936. Cloth, \$10.00.

This well known standard work has been entirely reset for its new edition. The individual and practical etiological attitude of the volume, as well as its field of usefulness, is too well known for elaboration. Only direct comparison with the previous 1932 edition can show the numerous changes in text and illustrations. Particularly noteworthy, however, are the enlarged and altered chapters dealing with virus infections, vitamin deficiencies, and endocrine disturbances. Not the least of its merits is the excellent reproduction of its illustrations.

IRVING M. DERBY

Royat Treatment in Cardiovascular Disease By Pierre N. Deschamps, M.D. Octavo of 108 pages. Baltimore, William Wood & Company, 1935. Cloth, \$2.00.

With remarkable clarity, Deschamps presents the case for the treatment of hypertension, cardiac insufficiency, angina pectoris and irritable arterial states by carbon dioxide baths. He calls upon a rich familiarity with clinical cardiology for guidance, and very thoroughly discusses the pharmacodynamics

Books

Books for review should be sent directly to the Book Review Department at 1313 Bedford Avenue Brooklyn, N. Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

A Text-Book of Neuro-Anatomy By Albert Kuntz, M.D. Second edition, thoroughly revised. Octavo of 519 pages, illustrated. Philadelphia, Lea & Febiger, 1936. Cloth, \$6.00.

A textbook to be successful, must be kept up to date by fairly frequent new editions to maintain its popularity. This volume, the second edition, is such an attempt. It can best be described as a real effort to simplify the study of the nervous system. In its 26 chapters, very thoroughly integrated, and pursuing a very careful plan based on the appreciation of fundamentals, this concept of simplicity is attained.

As in all works on neuro-anatomy, the heart of the work is in its illustrations—a total of 307 drawings decorating its pages. References pertinent to the subject are found at the end of each chapter. To the student the clear concise summary at the end of every chapter will be welcome.

The book is of a handy size, and can be carried about easily in a brief case. We feel that Dr. Kuntz has improved definitely on his earlier edition, and that the student will be pleased with the results of his second effort.

HAROLD MERWARTH

An American Doctor's Odyssey Adventures in Forty-five Countries. By Victor Heiser, M.D. Octavo of 544 pages. New York, W. W. Norton & Company, Inc., 1936. Cloth, \$3.50.

A remarkably interesting narrative of a busy doctor's life in odd corners of the world, adventures in forty-five countries Dr. Heiser calls it. The great public health battle in the Philippines and the fight waged by the Rockefeller Foundation on tropical diseases and plagues are interestingly told. Dr. Heiser is always at the front, waging war on malaria, leprosy, cholera, smallpox, beri-beri at their very sources in the vermin infested East. The ancient scourges of mankind are now almost under control, because medicine has tracked down rats, fleas, mosquitoes and the like with persistence and ingenuity worthy of story book detectives. Dr. Heiser is the super Sherlock Holmes of modern tropical medicine.

The chapter on smallpox is the most powerful indictment of the antivaccinationist ever written. The opening chapter on the Johnstown flood is pure literature, nothing better ever done. Rarely finding a tedious page, the physician will get a tremendous thrill, he will glow with pride and enlarge his knowledge of diseases little known to many of us and never seen. It is highly recommended for the medical profession, no one should miss it.

CHARLES A. GORDON

An Introduction to Psychological Medicine By R. G. Gordon, M.D., N. G. Harris, M.D. and J. R. Rees, M.D. Octavo of 300 pages. New York, Oxford University Press, 1936. Cloth.

In recent years greater attention is given to psychological medicine by those in charge of curricula in medical schools. No longer is the medical student expected to satisfy the requirements in his studies of psychiatry and allied subjects by simply visiting a State Hospital or attending lectures in psychiatry. He is now trained in medical psychology in its broadest implication, i.e. in psychiatry, psychopathology, the neuroses, and general maladaptations. The book under discussion is an admirable work that supplies a guide for the student of human behavior and its disorders. There are five sections in the book, devoted to psychology in relation to psychological medicine, psychopathology, psychoneuroses, psychoses, and mental deficiency. In reading the book, one is impressed with the thoroughness and with the philosophical approach of the authors in the treatment of the subject matter. It is the product of men who have had a very rich experience in their particular field. It is highly recommended to medical schools and to the general profession.

IRVING J. SANDS

Psychology of Sex. A Manual for Students By Havelock Ellis. Octavo of 377 pages. New York, Emerson Books, Inc., 1936. Cloth, \$3.00.

We are indebted to Havelock Ellis for another book on the psychology of sex. In substance this book presents in a com-

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W. 42nd St., N. Y. C.) postage prepaid. Order must be accompanied by remittance covering published price.

SUPPURATION IN THE PNEUMATIC ANTELABYRINTHINE PORTION OF THE PETROUS PYRAMID

HENRY K. TAYLOR, M D, F A C P, *New York City*

From the Roentgen Ray Department, Beth Israel Hospital, Dr I S Hirsch, director

Within recent years, more attention has been focused on the subject of suppurative lesions in the petrous portion of the temporal bone than heretofore. Since the symptom complex described by Kopetzky¹ in 1931, suppurative lesions are being recognized clinically, and because of clinical variations, considerable differences of opinion almost bordering on confusion have resulted. Variations in the interpretation of roentgenograms have also contributed in no small measure to this confusion.

To help clarify many mooted points of this subject, a comprehensive symposium was held before the American Otological Society in Toronto in May 1935.²

From an anatomical standpoint, the petrous portion of the temporal bone may be pneumatic, diploetic, mixed, and also have compact bone. The pneumatic bone may have small or large cells, or both. In the mixed type, the extent of pneumatization may vary considerably. The pneumatic cells may be diffuse, or in isolated groups, the latter appearing as foci surrounded by areas of diploetic or compact bone. The pneumatization may or may not extend to the very tip of the petrous pyramid. The symptomatology and the roentgen findings will vary, depending upon the extent and location of the af-

ected pneumatic structure. Guild³ has ably pointed out the wide range of variation in size, shape, and structure of the normal petrous pyramid.

This presentation deals only with the petrous pyramid which contains pneumatic structure, the pneumatic cells extending into that portion of the pyramid anteromedial to the labyrinth, irrespective of whether pneumatization is complete or incomplete.

Guild,³ quoting Jones, comments on the erroneous descriptive term of *petrous apex*. The labyrinth is practically the only constant in the pyramid and it should be used as a basis for terminology. Hence the term antelabyrinthine, as suggested by Jones,⁴ for that portion of the pyramid anteromedial to the labyrinth, is much better than the incorrect one of petrous apex. The antelabyrinthine portion of the pyramid, which may be two cm in length, has been referred to as the petrous apex. Fowler⁵ criticizes the inaccuracy of the term petrous apex, for all men are not agreed on just what is included in the petrous apex. He includes that portion of the pyramid anterior and medial to the arcuate eminence, as petrous apex.

Wilson⁶ studied the petrous pyramids in fifty children, aged five weeks to fifteen years, and described the petrous

and therapeutic applications of this well-known continental hydropathic treatment.

He cites the experience with CO₂ baths at Spa in Belgium, and Bad Nauheim in Germany, but deals especially with the "cure" at Royat in the Auvergne (France). Americans, physician and lay-man alike, are notably luke-warm towards spa treatments, but this study can be recommended as a frank scientific review of the CO₂ therapy. Now that our own Saratoga spa presents this method of treatment, we should particularly know what others have accomplished.

A personal visit to Royat has made the perusal of this little volume a special pleasure.

FRANK BETHEL CROSS

The Toxaemias of Pregnancy By Dame Louise McIlroy, M.D. Octavo of 355 pages. Baltimore, William Wood & Company, 1936. Cloth, \$5.00.

Toxemia of pregnancy is today one of the most baffling problems of the obstetrician as well as internist and pathologist. In this volume the subject is well presented and discussed from all angles. The vagueness of present day knowledge of toxemia is candidly admitted, and the many viewpoints found in current literature are concisely presented and evaluated. Throughout the work the conservative attitude of the author as to therapeutics and management is emphasized. The arguments of this attitude are firmly supported by statistics of her own and others.

The problem is, for the most part, presented as a clinical one. Stress is placed upon prophylaxis, and many practical points as to prevention and treatment of the conditions, as well as the management of the obstetrical issue, make the reading of this work well-worth while.

WILLIAM C. MEAGHER

Principles of Chemistry An Introductory Textbook of Inorganic, Organic and Physiological Chemistry for Nurses and Students of Home Economics and Applied Chemistry. By Joseph H. Roe, Ph.D. Fourth edition. Octavo of 475 pages, illustrated. St. Louis, The C. V. Mosby Company, 1936. Cloth \$2.75.

This book on chemistry for nurses, and students is so well written that it is also suitable for medical practitioners and their technicians. It contains 475 pages and thoroughly describes in simple English, inorganic, organic, and physiological chemistry. The questions at the end of each chapter, if followed by the student, are of great value to keep his knowledge organized. The many experiments can be easily

performed by the student, and his own notes added on the blank pages provided in Part II of the Laboratory experiments.

We recommend this book.

M. Axt

Endocrinology in Modern Practice By William Wolf, M.D. Octavo of 1018 pages, illustrated. Philadelphia, W. B. Saunders Company, 1936. Cloth, \$10.00.

The great advances made by research workers in the field of endocrinology have aroused the keenest interest of practicing physicians. This would justify the writing of an up to date, comprehensive textbook, provided that the writer masters his difficult subject. This task requires not only first hand knowledge of the physiology and pathology of the endocrine glands, but also ample clinical experience in the evaluation and interpretation of the manifold clinical symptoms as well as in the correct application of modern glandular therapy. The prerequisite of this double task is personal experience in both the laboratory and the clinical aspects of endocrinology. The most studious reading of endocrine literature can hardly substitute for deficiencies in either field, nor can the reader be satisfied by the impartial rendering of controversial opinions, without the authoritative viewpoint of the textbook writer whose mature judgment is meant to guide the less highly specialized physician.

Dr. Wolf's *Endocrinology in Modern Practice* is an able presentation of modern endocrine literature gathered by a scholarly student of this important branch of clinical medicine.

M. A. GOLDZIEHER

Mental Nursing (Simplified) By O. P. Napier Pearn, M.R.C.S. Second edition. 16mo of 328 pages, illustrated. Baltimore, William Wood and Company, 1936. Cloth. \$2.00.

This edition of a compend, written in a unique style of short factual sentences with technical words separated into syllables, has been enlarged and revised without altering its simple outline. It includes summaries of medicine, nursing, hygiene, a good discussion of mental diseases, and chapters on passing examinations. The mental classifications, administrative features, and legal aspects are British but have been parenthetically noted as such for the most part. Instructors of student nurses in any subject should have the opportunity of utilizing its practical viewpoint. The intense simplicity should assist most undergraduate students. Openly written for examination study, it is well recommended for "cramming."

IRVING M. DERBY

SUPPURATION IN THE PNEUMATIC ANTELABYRINTHINE PORTION OF THE PETROUS PYRAMID

HENRY K TAYLOR, M D , F A C P , *New York City*

From the Roentgen Ray Department, Beth Israel Hospital, Dr I S Hirsch, director

Within recent years, more attention has been focused on the subject of suppurative lesions in the petrous portion of the temporal bone than heretofore. Since the symptom complex described by Kopetzky¹ in 1931, suppurative lesions are being recognized clinically, and because of clinical variations, considerable differences of opinion almost bordering on confusion have resulted. Variations in the interpretation of roentgenograms have also contributed in no small measure to this confusion.

To help clarify many mooted points of this subject, a comprehensive symposium was held before the American Otological Society in Toronto in May 1935.²

From an anatomical standpoint, the petrous portion of the temporal bone may be pneumatic, diploetic, mixed, and also have compact bone. The pneumatic bone may have small or large cells, or both. In the mixed type, the extent of pneumatization may vary considerably. The pneumatic cells may be diffuse, or in isolated groups, the latter appearing as foci surrounded by areas of diploetic or compact bone. The pneumatization may or may not extend to the very tip of the petrous pyramid. The symptomatology and the roentgen findings will vary, depending upon the extent and location of the af-

ected pneumatic structure. Guild³ has ably pointed out the wide range of variation in size, shape, and structure of the normal petrous pyramid.

This presentation deals only with the petrous pyramid which contains pneumatic structure, the pneumatic cells extending into that portion of the pyramid anteromedial to the labyrinth, irrespective of whether pneumatization is complete or incomplete.

Guild,³ quoting Jones, comments on the erroneous descriptive term of *petrous apex*. The labyrinth is practically the only constant in the pyramid and it should be used as a basis for terminology. Hence the term antelabyrinth, as suggested by Jones,⁴ for that portion of the pyramid anteromedial to the labyrinth, is much better than the incorrect one of petrous apex. The antelabyrinthine portion of the pyramid, which may be two cm in length, has been referred to as the petrous apex. Fowler⁵ criticizes the inaccuracy of the term petrous apex, for all men are not agreed on just what is included in the petrous apex. He includes that portion of the pyramid anterior and medial to the arcuate eminence, as petrous apex.

Wilson⁶ studied the petrous pyramids in fifty children, aged five weeks to fifteen years, and described the petrous

and therapeutic applications of this well-known continental hydropathic treatment

He cites the experience with CO₂ baths at Spa in Belgium, and Bad Nauheim in Germany, but deals especially with the "cure" at Royat in the Auvergne (France). Americans, physician and lay-man alike, are notably luke-warm towards spa treatments, but this study can be recommended as a frank scientific review of the CO₂ therapy. Openly written for examination study, it is well recommended for "cramming."

IRVING M. DERBY

a perforation of the superior wall of the pyramid associated with an epidural abscess may sometimes be detected in the oblique view of the skull. This cannot be detected in a film of the base of the skull, but may be detected in a P-A view.

Fowler⁵ urges the recording of the exposure factors in each case, so that the same technic may be used in re-examination. He cites an instance with an error in interpretation because the technical factors were not identical in two different examinations.

From the roentgen standpoint, there are two types of suppurative lesions occurring in the antelabyrinthine portion of the pyramid. One type is manifested by a destructive lesion, and the other by a productive lesion.

When the lesion is of a destructive nature, there is a coalescence of cells, trabeculae are usually not visible, although they may appear fragmented. The antelabyrinthine area shows a decrease in density, while the labyrinthine and postlabyrinthine areas show an increase in density. When the halistheresis is pronounced the contours of the antelabyrinth may be faintly visualized or not at all. The non-visualization of the antelabyrinth is no indication of a perforation.

When pneumatization in the antelabyrinth is incomplete, the pathology may not be readily recognized. The decalcification, which is sharply limited by the labyrinth, will be more diagnostic and more readily recognizable than small isolated areas of destruction. Areas of destruction, while present, may be obscured by the nonpneumatic bone. When the antelabyrinth is completely pneumatized, the changes are the same as found in a coalescent mastoiditis.

This lesion is relatively acute, and may occur with two different clinical pictures.

1. It may occur with an acute coalescent mastoiditis, or soon after as a complication following mastoidectomy (Fig 1). If drainage from the antelabyrinthine area, either through the ear canal or mastoid wound is interfered with, certain clinical signs and symptoms appear, which, if left alone, will terminate in a meningitis.

2. If drainage is not interfered with, no clinical signs or symptoms appear, this type may be referred to as subacute.⁸ (Fig 2). A normal convalescence follows, except that an otorrhea persists.

The otorrhea in the above two types may persist from the time of surgery, or, there may be complete healing of the wound with cessation of the aural discharge, and then reappearance of the discharge after a varying interval of time. In the type where drainage is adequate, is not interfered with, where no clinical signs or symptoms are present other than the discharge, *symptoms may suddenly appear indicating inadequate drainage*. This requires surgery as a life saving measure. It is conceivable that blockage of drainage may be of an evanescent nature. Alarming symptoms may be present and suddenly disappear with the institution of free drainage. The reverse may also happen.

From an anatomical standpoint, it is possible for a suppurative lesion in the antelabyrinth to appear as a complication to an acute otitis media.

When the lesion is productive in character, the entire pyramid shows an increase in density, the trabeculae may be thickened or no cells or trabeculae may be visible, a productive osteitis is present (Fig 3 and 4). A sclerosing process involves the pyramid. This is a chronic lesion. In many cases of chronic otorrhea, the focus of infection may be located in the antelabyrinthine portion of the pyramid. In this type, there are no symp-

Fig 2. Left antelabyrinth. Coalescence of cells—intense atrophy. Clinically Otorrhea following mastoid surgery, no other symptoms. Suppurative lesion with adequate drainage (subacute).

Fig 1 Right antelabyrinth. Coalescence of cells—intense atrophy. Clinically Suppurative lesion with inadequate drainage (acute)

apex as being "medial to the internal auditory meatus and the bony capsule of the cochlea and terminates at the synchondrosis of the basi-occipital and the sphenoid"

While most authors used the term of petrous apex erroneously, practically all referred to the same anatomical portion of the petrous pyramid—that portion anterior and medial to the labyrinth. In order to avoid confusion and to adopt a descriptive nomenclature, I believe the suggestion of Jones is an excellent one, and that the erroneous term *petrous apex* should be discarded in favor of the more accurate term *antelabyrinthine* portion of the pyramid or *antelabyrinth**. This excludes any pneumatic structure about the semicircular canals or cochlea coils of the otic capsule. These latter cells may be referred to as *labyrinthine* or *perilabyrinthine*, with further subdivisions as to exact location, proximity to the semicircular canals or cochlea coils, superiorly, inferiorly, anteriorly or posteriorly. For the cells lateral to the semicircular canals, (mastoid) Guild³ suggests the name of *postlabyrinthine* cells.

There are many ways of demonstrating the petrous pyramid on a roentgenogram. Each position for demonstrating the pyramid has value. The popular positions

used for demonstrating the suppurative lesions in the antelabyrinth are axial projections, of the base of the skull, and oblique views of the skull. With the axial projections, the petrous pyramids are rayed simultaneously. The ones commonly used are (1) inferosuperior, (2) superoinferior, and (3) posteroanterior with the pyramids projected into the orbits. In the oblique views of the skull, each pyramid is rayed singly and the popular positions are (1) Stenvers, and (2) reversed Stenver, or the Granger modification of the Arcelin position.

I prefer to use the inferosuperior projection of the base of the skull and the Granger modification of the Arcelin position for demonstrating the petrous pyramids. Dr Frederick M Law uses the superoinferior projection. I have found it easier to determine the extent and nature of the pneumatization in a film of the base of the skull. This position should be included in the routine examination of the mastoid process. I recommended this procedure five years ago and still find it very useful.⁷ Law concurs in this view. Fowler,⁸ Seydell,⁹ and others emphasize this. The literature reveals that many otologists and roentgenologists consider this procedure valuable and have incorporated it in their routine roentgen examination of the mastoid processes. Fowler,⁸ recommends that the P-A view be included.

When a complicating lesion is suspected in the antelabyrinthine portion of the pyramid, the routine roentgen examination should include the mastoid areas, a film of the base of the skull, and the pyramids in the Stenver or reversed Stenver position*.

A film at the base of the skull made at the time of the original mastoid examination, compared with a film of the base of the skull made at the time of an otitic complication, will immediately determine the presence or absence of a lesion in the antelabyrinthine area. In addition, the pyramid in the Stenver or reversed Stenver position will corroborate the findings. In the event that no suppurative lesion exists in the antelabyrinth,

* I usually employ the reversed Stenver position when I include an oblique view of the skull.

* Guild³ suggested the term *mediolabyrinthine*.

perforation of the superior wall of the pyramid associated with an epidural abscess may sometimes be detected in the oblique view of the skull. This cannot be detected in a film of the base of the skull, but may be detected in a P-A view.

Fowler⁵ urges the recording of the exposure factors in each case, so that the same technic may be used in re-examination. He cites an instance with an error in interpretation because the technical factors were not identical in two different examinations.

From the roentgen standpoint, there are two types of suppurative lesions occurring in the antelabyrinthine portion of the pyramid. One type is manifested by a destructive lesion, and the other by a productive lesion.

When the lesion is of a destructive nature, there is a coalescence of cells, trabeculae are usually not visible, although they may appear fragmented. The antelabyrinthine area shows a decrease in density, while the labyrinthine and postlabyrinthine areas show an increase in density. When the halisteresis is pronounced the contours of the antelabyrinth may be faintly visualized or not at all. The non-visualization of the antelabyrinth is no indication of a perforation.

When pneumatization in the antelabyrinth is incomplete, the pathology may not be readily recognized. The decalcification, which is sharply limited by the labyrinth, will be more diagnostic and more readily recognizable than small isolated areas of destruction. Areas of destruction, while present, may be obscured by the nonpneumatic bone. When the antelabyrinth is completely pneumatized, the changes are the same as found in a coalescent mastoiditis.

This lesion is relatively acute, and may occur with two different clinical pictures.

1 It may occur with an acute coalescent mastoiditis, or soon after as a complication following mastoidectomy (Fig 1). If drainage from the antelabyrinthine area, either through the ear canal or mastoid wound is interfered with, certain clinical signs and symptoms appear, which, if left alone, will terminate in a meningitis.

2 If drainage is not interfered with, no clinical signs or symptoms appear, this type may be referred to as subacute.⁸ (Fig 2). A normal convalescence follows, except that an otorrhea persists.

The otorrhea in the above two types may persist from the time of surgery, or, there may be complete healing of the wound with cessation of the aural discharge, and then reappearance of the discharge after a varying interval of time. In the type where drainage is adequate, is not interfered with, where no clinical signs or symptoms are present other than the discharge, *symptoms may suddenly appear indicating inadequate drainage*. This requires surgery as a life saving measure. It is conceivable that blockage of drainage may be of an evanescent nature. Alarming symptoms may be present and suddenly disappear with the institution of free drainage. The reverse may also happen.

From an anatomical standpoint, it is possible for a suppurative lesion in the antelabyrinth to appear as a complication to an acute otitis media.

When the lesion is productive in character, the entire pyramid shows an increase in density, the trabeculae may be thickened or no cells or trabeculae may be visible, a productive osteitis is present (Fig 3 and 4). A sclerosing process involves the pyramid. This is a chronic lesion. In many cases of chronic otorrhea, the focus of infection may be located in the antelabyrinthine portion of the pyramid. In this type, there are no symp-

Fig 2. Left antelabyrinth. Coalescence of cells—intense atrophy. Clinically Otorrhea following mastoid surgery, no other symptoms. Suppurative lesion with adequate drainage (subacute).

Fig 3 Left Pyramid No pneumatic structure visible. There are productive changes involving the pyramid. Clinically Persistent otorrhea following mastoid surgery. Mastoidectomy two years previously. Suppurative lesion in antelabyrinthine area with adequate drainage (chronic).

In addition to the findings just described, the petrous pyramid shows changes from the normal with *any otitic infection*, even though no suppurative lesion in the pyramid exists. To quote Fowler,¹⁰

The air cells communicate with one another and, more important still, they communicate with the middle ear, so that if there is an inflammatory process in the middle ear there is usually more or less inflammatory reaction in the mastoid and the petrous cells. That is, with every otitis media there is always more or less mastoiditis, and if there are cells in the petrosae, always more or less petrositis. The important point is that infection may well be apparent in roentgenograms, but x-ray changes in the petrosae do not necessarily mean operative petrositis any more than x-ray changes in the mastoid necessarily mean operative mastoiditis.

It is because of the variations in the appearance of the pneumatized pyramid, in the presence of an otitic infection,¹¹

Fig 4 Same as Fig 3 in reversed Stenver position also showing the productive bone changes involving the left pyramid.

toms other than the otorrhea. There is no interference with drainage. When drainage is interfered with, alarming symptoms present themselves.

In the type, with a persistent otorrhea, an acute reinfection may occur. When this happens, while drainage was formerly free, the reinfection causes an obstruction to interfere with drainage. Jones⁴ considers the reinfection of a chronic or prolonged process with obstruction to drainage as the most dangerous type

without a complicating suppurative lesion in the antelabyrinth, that variations in opinion have resulted.

A perforation in the antelabyrinthine area of the pyramid may occur when a suppurative lesion is present. When the perforation involves the superior surface, it may be recognized in the reversed Stenver position, and also in the P-A view. It cannot be recognized in a film of the base of the skull.

A perforation through any surface

other than the superior, cannot be detected unless a contrast substance which had been injected into the pyramid, escaped into the cranial cavity or into the posterior pharyngeal wall. The contrast substance can be injected into the fistulous tract if present, or through the drill hole in the Almour operation.¹ I have never seen a perforation along the base or anterior surface of the pyramid with an extension of the lesion into the posterior pharyngeal wall.

In one instance, I observed a perforation through the posterior surface of the pyramid with the formation of a cerebellar epidural abscess. The contrast substance was instilled into the fistulous tract and found an exit into the posterior cranial fossa.

The contrast substance entering into the cranial cavity may be localized and walled off at the site of the perforation, or it may enter all the fossae along the base of the skull. When it extends posteriorly, it usually dissects the layers of the tentorium and is not found below it.

When the contrast substance is found below the tentorium, the prognosis is bad.

Conclusions

1 The term petrous apex should be abandoned. The subdivisions of the pyramid should be designated antelabyrinth, labyrinth or perilabyrinth, and postlabyrinth.

2 The pneumatic structure in the petrous pyramid can be demonstrated roentgenographically. Pathological changes occurring in the antelabyrinth following an otitic infection, may be acute, subacute or chronic. The acute and subacute varieties show destructive changes while the chronic variety shows productive changes in the antelabyrinth.

3 The roentgenogram reveals changes in the appearance of the antelabyrinth with every otitic infection. These changes are not necessarily due to a suppurative lesion in the antelabyrinth.

LATEST WRINKLE OF NAZI PERSECUTION

The repercussions of Nazism seem endless. The medical refugees from Nazi hostility flood near-by lands, of course, and Czechoslovakia has naturally been deluged. Native doctors protested, so the government ruled that a medical practitioner must be of Czechoslovakian nationality, by birth, naturalization or marriage. Marriage, like charity, may cover a multitude of sins! As told in the foreign correspondence of the *Medical Record*, the new law brought about a situation unique in the annals of medical practice. Many doctors married Czechoslovakian citizens, men or women, as the case

required, and thus complied with the laws on licensure. Later on this practice degenerated into a real business. A young doctor would marry a Czechoslovak lady "for a consideration", he would obtain his license on the grounds of his diploma plus the marriage certificate, and as soon as his shingle was out he would divorce his partner and so remain not only a full-fledged practising physician, or surgeon, but also a fully legal Czechoslovak citizen. Until now the government has not yet found a solution to this aspect of the problem.

LITTLE RECOGNIZED TYPES OF ALLERGY

T WOOD CLARKE, A B , M D , *Utica*

Thirty-two years have passed since Theobald Smith,¹ in his studies of diphtheria, ran out of guinea pigs, reinoculated with horse serum several that had previously been given antitoxin, and was astonished to find that, whereas the first dose had been innocuous, the second caused sudden death. It is twenty-six years since Meltzer,² in a half column article, called attention to the similarity of the symptoms shown by these animals dying of anaphylaxis to those of human beings with asthma, and suggested that asthma was a mild form of anaphylactic shock. Twenty-four years ago Schloss³ put some milk on a scratch on the arm of a child that had an idiosyncrasy against milk and saw the prompt production of a wheal.

From these three observations, in the last score of years has grown an entirely new branch of medicine, a completely novel conception of many previously unexplainable diseases and another class of recruits to our ever-increasing army of specialists. Allergy and the allergist are the outcome of these studies of Smith, Meltzer, and Schloss.

The recognition of allergy as a new specialty in medicine and the acceptance of the principles underlying it as a means of curing many diseases previously considered incurable, has met in some quarters the same opposition as did the introduction of vaccination by Jenner, of antiseptics by Lister, and clean obstetrics by Holmes. During the last twenty years, however, allergy has come into its own, and today the physician who will attempt to treat a case of asthma, or of eczema, without giving the patient the opportunity of having his case studied as to his allergic idiosyncrasies may well be considered to be giving his patient about as fair a deal as does he who sets a broken thigh without having recourse to the x-ray, or neglects to give antitoxin in diphtheria.

Ten years ago not one physician in a

hundred knew the meaning of the word allergy. Today there are few indeed so reactionary that they will not admit that in cases of asthma, hay fever, eczema, urticaria, and angioneurotic edema knowledge of the etiology of the disease can often be obtained by a series of skin tests, and in many cases these recurring intractable diseases can be cured by following up the knowledge so obtained. The value of allergic studies for these five diseases is so well-established that today it needs no brief. We all know it as a fact whether we make use of that knowledge by referring our cases to an allergist for scientific study, or go on with the purely palliative methods of treatment of the last century.

Most of the medical profession, however, when thinking of the allergic diseases picture in their mind these five conditions and stop there. Very few appreciate how far afield the immense amount of clinical research in allergy has gone and how much evidence has been accumulating pointing to the allergic origin of some of our most common and most puzzling clinical entities.

An allergic reaction, or shock, is caused by the absorption into the system of a foreign protein to which the patient, through inheritance and previous environment, has become sensitized. This protein may be acquired by inhalation, ingestion, or contact, or it may be generated in the body itself. It may be inspired as the pollen of flowers, dander, or hair of animals, or furs, feathers, clothing, scents, powders or dust, and in fact any protein which may be present floating in the air. It may be ingested in the form of foods. It may gain entrance by direct contact with the skin as in the case of flowers, furs, clothing, and dyes. Lastly, it may be generated in the patient's own body, a result of digestion, or more commonly, as the products of bacterial or fungus action in cases of focal infection. When the specific foreign

*Read before the joint meeting of the Utica and Syracuse Academies of Medicine,
September 17, 1936*

protein gains entrance to the body of the person previously sensitized to it, one or more of three things may occur—local edema, smooth muscle spasm or increased glandular secretion. These changes can take place in any part, or any tissue, of the body and, according to the nature and the location of the reaction, many and various clinical symptoms may develop.

While all physicians who keep abreast of the progress of medical science today recognize the true nature of asthma and seasonal hay fever, many do not appreciate that several other diseases of the respiratory tract may be of allergic origin.

The most common of these is the symptom complex, long known to the rhinologist as hypertrophic, or vasomotor, rhinitis, and to the allergist as perennial hay fever. The symptoms which may be recurrent or almost constant have little relation to the season. The patient who previously may have been quite well suddenly has an attack which, if it had occurred in June or in August, would have been diagnosed hay fever. There is burning and itching of the eyes, nose, throat, and roof of the mouth. There is lacrimation, sneezing, and a profuse watery discharge from the nose. The eyes may be swollen shut and the nose enlarged and turgid. On examination the nasal mucous membranes are swollen, boggy, and, instead of being red as in an acute rhinitis, they are of a glistening pearl gray. The discharge from the nose, if stained, is found to contain a great number of eosinophiles. The turbinates are swollen, nasal drainage is obstructed, and, if the condition has been of long standing, there are usually nasal polypi and chronic swelling of the lining of the paranasal sinuses.

This is the type of case that has been the *bête noire* of the rhinologist. Turbinates have been removed, polypi have been snared, sinuses have been drained, and in a few months the patients have returned with the story that after a few weeks of partial relief the symptoms have returned as bad, or even worse, than before. The general opinion today is that all of these cases are of allergic origin. Rhinologists today appreciate this and

are referring them more and more to the allergist to find the underlying cause of the condition. Polypi are not the cause of the nasal turgescence, but are the result of the edema which is but an allergic reaction to some foreign protein. While most of these cases are activated by inhalation of the emanation of hairs, feathers scents, especially orris root, or wave sets as flaxseed, or gum acacia, or dust, others can be caused by the ingestion of some food protein. The most common food offender in this disease is wheat, although eggs come a close second. Other cases seem to be the result of allergic sensitivity to bacterial toxines, produced in foci of infection, perhaps in the head, perhaps in some distant part of the body.

Rhinological operations upon these patients are unjustified unless the patient has first been studied from the allergic viewpoint and either the offending source of irritation eliminated or the patient desensitized by proper treatment based upon the allergic findings. After this has been done, if there still remain pathological conditions causing nasal obstruction, operation may be done with fair hope of a permanent cure. Without the removal of the allergic cause, the operation is no more logical than is the constant mopping up of a wet floor without mending the hole in the roof.

The allergic reaction, if it extends to the pharynx, may cause redness and burning of the throat often mistaken for recurrent pharyngitis, and if it reaches the larynx may result in edema of that organ. It is interesting to see what a large proportion of allergic patients give a history of croup in infancy and childhood. There has been very little work done on spasmodic croup as an allergic manifestation, but it is very possible that some investigation along this line will add this fearsome, if harmless, affection of childhood to the allergic family.

Although, when the bronchial tubes are involved, the usual result is asthma, the reaction may take another form and produce a dry irritating cough usually diagnosed bronchitis. When one has seen an infant suffering from repeated attacks of bronchitis entirely alleviated by removing a canary from his room, or

a boy coughing day and night for four days every time he touches a cat, one wonders how many more cases of recurrent and chronic bronchitis may not be due to similar easily remedial causes

One allergist of wide experience* has gone so far as to describe what he calls allergic pseudobronchopneumonia. In these cases the child is taken suddenly ill with fever, dyspnea, cyanosis, and rales in his chest. In fact he has all the typical symptoms of a severe bronchopneumonia. Unlike the true disease, however, the symptoms all disappear in from twelve to thirty-six hours and more rapidly if treated with ephedrine or adrenalin. These attacks may occur at frequent intervals. He suggests that in all cases where children have frequent attacks of bronchopneumonia of short duration the possibility of an allergic origin should be given due consideration.

There are few diseases which in the aggregate cause more hours of maternal worry than does that which is commonly called catching cold. "Colds" in frequency probably exceed all other illnesses put together. Still how little we really know of the cause of the disease and how little we can do to prevent and cure it. Rhinorrhea, pharyngitis, laryngitis, bronchitis, pneumonitis are all grouped under this all embracing term. Most of these attacks are probably true infections. Yet when one considers that every symptom complex grouped under this classification can be reproduced in allergic patients by the specific protein to which they are sensitive, one naturally wonders how many of our sufferers from repeated "colds" are really children undergoing an allergic reaction. It would seem likely that if every case of recurring colds were considered as at least a possible case of allergy, and investigated from this viewpoint much childhood suffering and maternal anxiety might be prevented. It is certain that not all respiratory affections are allergic in origin. It is just as certain that many, now not recognized as such, are true allergies.

If the allergic manifestations appear in the gastrointestinal system the symptoms vary with the location and the character of the lesions. All are familiar with the sudden edema of the lips and tongue

which will occur in the child with an idiosyncrasy to egg almost immediately this food comes in contact with the child's mouth. Few, however, appreciate that many of the cases of aphthous stomatitis, popularly called canker sores, are of allergic origin and can be prevented and cured by identifying the offending protein and removing it from the dietary. Such cases occurring only once or at rare intervals, are probably of infectious origin and may even be mild forms of Vincent's Angina. The troublesome cases of recurring canker sore, however, which keep the mouth uncomfortable more or less constantly and are generally blamed on indigestion, or constipation, should be held under suspicion of being of allergic origin and treated accordingly. If the patient shows other allergic affections this precaution becomes imperative.

If an allergic reaction can manifest itself by swelling of the lips, or ulceration of the cheeks or tongue, it is reasonable to suppose that after the offending protein has been swallowed it will continue to produce similar changes in the stomach and intestines. Clinical observation has confirmed this supposition. It has been amply proven that the three types of the allergic reaction—local edema, muscle spasm, and hypersecretion—may all occur in the stomach and intestines in the allergic patient upon the ingestion of the offending protein.

The extensive studies of many careful observers prove beyond a doubt that many of our cases of chronic and recurring digestive disturbances are due to swelling of the walls of the intestines and spasm of the musculature of the bowel as part of an allergic reaction. Occasionally cases occur in which there is a condition of angioneurotic edema of the intestinal wall so marked that a tumor-like mass can be picked up in the fingers. In these cases there may be complete closing of the intestinal lumen and all the evidences of acute obstruction. These symptoms usually disappear in twenty-four hours, or more rapidly following an injection of adrenalin. In other cases the allergic lesions may cause abdominal pain and tenderness, either general or localized, easily mistaken for an involvement of the ap-

pendix or gall-bladder. In these cases, if the offending protein can be identified; and it is usually one of the common ones as wheat, milk or eggs, and eliminated from the diet, the symptoms promptly disappear to recur immediately following the reingestion of the same food. In those cases of supposed chronic appendicitis, or gall-bladder disease, where the patient has returned following an operation with the cheering news that the symptoms are as bad as ever, the surgeon often could have saved himself much chagrin if he had thought a little more about the possibility of gastrointestinal allergy before he advised operation. Of course when one has definite symptoms of an acute appendicitis, or cholecystitis, one cannot afford to waste time required for an allergic investigation and immediate operation is indicated, but in many of the indefinite subacute and chronic cases where operations are recommended chiefly because the patient has suffered recurring attacks of abdominal pains and the physician is at a loss to know what further to do, one should at least inquire carefully into the question of an allergic family and past history, and give some thought as to whether this particular patient may not have a better chance of alleviation if placed in the hands of an allergist rather than of a surgeon. Many chronic dyspeptics have been completely cured of their symptoms and have been saved the danger, discomfort, and expense of a useless abdominal operation by the allergist discovering that he had an idiosyncrasy against some article in his diet.

There are few common diseases concerning which we are etiologically so thoroughly at sea, or in whose treatment we receive more discouraging setbacks than in the case of gastric and duodenal ulcers. Some interesting observations suggest that in some of these cases at least allergy may be a factor.

In 1925 Ivy and Shapiro⁵ sensitized dogs with a pyloric pouch and rabbits to various proteins. After they had become sensitized he injected the same protein into the gastric mucosa. In a few days the animals developed typical punched-out ulcers indistinguishable from peptic ulcers in man. Control animals that had

not been previously sensitized showed no such ulcers.

In 1931 Kern and Stewart⁶ reported thirty-two unselected cases of duodenal ulcer. Fifty per cent of them gave either a family or personal history of allergic disease, and sixty per cent gave one or more reactions to skin tests. In a considerable number of these cases the symptoms of ulcer could be relieved by removing the offending protein from the diet and would return immediately upon its reingestion.

Recently Gay⁷ of St. Louis reported a series of peptic ulcers studied from the allergic viewpoint by means of skin tests, elimination diets and the leukopenic index. He was able to control the symptoms of his patients by regulating the diet according to the results of his allergic studies. It is interesting to note that several of his cases who had made no progress on the Sippy diet were found to be hypersensitive to milk. These cases showed prompt improvement when milk was eliminated and they were fed such heterodoxical foods as cauliflower, apples, string beans, cabbage, and tomatoes.

In the absence of personal experience with the allergic study of gastric and duodenal ulcer one is loath to wax enthusiastic. Certainly, however, these findings are most suggestive and hold out hopes of results more beneficial than are usually obtained by the methods of treatment now in vogue. If a few more cases of peptic ulcer were referred to the allergist for investigation, it is possible that much new light could be thrown upon the puzzling question of etiology and treatment of the disease.

When the allergic reaction takes the form of hypersecretion of the intestinal glands large amounts of mucus are poured into the bowel. If to this is added smooth muscle contractions we get the typical symptom complex known as mucous colitis. Since Vaughn⁸ first (1922) described mucous colitis as an allergic disease, students of allergy have come more and more to believe that many of these cases are the direct result of the ingestion of food to which the patients are sensitive, and some have gone so far as to say that all such cases are allergic. If you can relieve these chronic

sufferers by such a simple procedure as elimination of egg from the diet and save them from the discomfort and nuisance of the popular and fashionable high colonic irrigations, they will rise up and call you blessed

If the intestinal congestion and ulceration due to allergy is extensive, it may be accompanied by the extravasation of blood. Lintz⁹ has found occult blood in the stools of a large number of patients following attacks of asthma, and other writers have described macroscopic hemorrhages from the bowel which they believed were due to an allergic reaction of the intestinal mucous membrane

If the allergic reaction occurs inside the cranial cavity it may cause definite and even violent neurological symptoms. If it takes the form of contraction of the muscles of the cerebral arteries, the result will be a local cerebral anemia. If it shows itself as an urticaria, or angio-neurotic edema of the brain or meninges, the pathological condition becomes to all intents and purposes an acute evanescent brain tumor.

Careful observation during the past dozen years has shown that practically any one of the cardinal symptoms of brain tumor may occur intermittently in patients as a result of an allergic condition. A few observers have explained certain peculiar forms of transient paralysis by attributing them to either arteriospasm, or local brain edema, of allergic origin. Others have produced evidence that cases of recurrent vomiting, and especially the condition of childhood called cyclic vomiting, a disagreeable symptom complex which has never been adequately explained, are really due to allergic reactions in the brain, or directly on the gastric mucous membrane.

The third manifestation of brain pressure, headache, is one of the most common, if not universally accepted results of allergy. It is seventeen years since three French investigators¹⁰ called attention to the similarities between migraine and asthma and urticaria, in its recurrence without apparent cause, and its association with other allergic diseases. Vaughan¹¹ a few years later proved conclusively that a considerable percentage of cases of migraine are allergic and that

after the offending protein, most commonly wheat, has been discovered the attacks can be prevented and produced at will by withholding, or feeding it. Other symptoms of increased cerebral pressure, scintillating scotomata, dizziness, and vomiting which so frequently accompany the headache in migraine, all point to an acute, if transient, brain tumefaction. It is difficult to imagine any process which could produce a brain tumor, coming on suddenly, disappearing as suddenly, and then recurring at regular intervals except the acute edema of an allergic shock. Opinions differ as to the percentage of cases of migraine which are allergic varying according to the enthusiasm of the author all the way from fifteen to one hundred per cent.

The fourth classical symptom of brain pressure, convulsion, as a result of an allergic edema of the brain is one in which I have been intensely interested for the last five years in the form of infantile convulsions and epilepsy. There has not been a great deal of work done on infantile convulsions, but what has been done points strongly to allergy as a cause in some cases. I vividly recall one baby who was having from one to five convulsions a day. This child gave positive skin reactions to oats, beef, apple, date, celery, spinach, chicken, duck and goose feathers, dog hair, and cottonseed. During the two weeks consumed in testing, the child remained in the hospital and continued to have several convulsions daily. On completing the study and eliminating the offending proteins from the diet and environment, the attacks ceased immediately and did not recur during the remaining ten days of hospitalization.

Epilepsy is generally considered a hopelessly incurable disease and a condition the true etiology of which has never been discovered. The truth of the matter is that probably the symptom complex which we call epilepsy is a manifestation of several quite distinct and diverse pathological processes. The work of some dozen investigators in various parts of the world point strongly to the probability that at least some cases of epilepsy are allergic in origin and can be completely cured if treated as such. An acute localized cerebral edema due to

allergy would seem theoretically as rational an explanation of the symptoms of epilepsy as any that has as yet been offered. Recently Davidoff and Kapeloff¹² have carried out some interesting experiments on dogs. They sensitized the left cerebral motor area in several animals by first injury to the region, and then injecting horse serum or egg albumin. Following this, whenever horse serum or egg albumin was injected intravenously either transient paralysis or convulsive motions appeared in the right legs.

My personal observations confirm the relation between epilepsy and allergy for in several cases I have discovered in typical cases of idiopathic epilepsy definite protein hypersensitiveness, and by following out appropriate treatment as the result of an allergic investigation have been gratified to procure a complete cure. My first case of this kind which started my interest in allergic epilepsy, was that of a young girl who had had epileptic attacks for four years finally recurring twice a week. As she also had asthma I did skin tests on her. She was sensitive to radish, cheese, cottonseed, and cattle hair. The foods were eliminated from her diet and cotton from her environment. As she lived on a farm, cattle could not be avoided and for eight months she received weekly inoculations with cattle hair. Not only was she cured of her asthma, but to my astonishment her epileptic attacks rapidly decreased in frequency, and she has had no convulsions since November 1931. Other cases, perhaps less dramatic than this, have convinced me that some cases of epilepsy are in truth cerebral allergy, and if they can be recognized and treated before organic brain degeneration has set in complete cures may be obtained.

No one claims to be able to cure all cases of recurrent headache and epilepsy by treating them as manifestations of cerebral allergy. On the other hand, if we can benefit even a small percentage of these pitiful creatures doomed to a lifetime of suffering and misery, by the simple procedure of finding to what proteins they are sensitive and eliminating them we have done a work in which we can take great satisfaction. Is it fair to deprive these sufferers of this chance?

A common concomitant of hay fever is itching and running of the eyes. Vernal conjunctivitis is simply an allergic reaction to a pollen with, or without, the accompanying nasal symptoms. Various authors have described cases of blephoritis, conjunctivitis, scleritis, and corneal ulcer due to an idiosyncrasy against some food, orris root or some cosmetic. Where any eye lesion recurs, either seasonally or at irregular intervals, its allergic origin should be kept in mind.

Arthritis is a term which covers a series of clinical entities varying greatly both as to etiology and the course of the affliction. In the septic joint, caused by direct infection of such organisms as the streptococcus or the gonococcus the etiological factor is easily discovered. In many other types, however, although among the most common of human afflictions our knowledge of the etiological factor is meager. We know little as to the etiology of such a common disease as acute articular rheumatism, except that it seems to be associated with diseased tonsils or bad teeth. When it comes to rheumatoid arthritis, or arthritis deformans, our ignorance is abysmal.

The theory has been propounded that acute rheumatic fever is closely related to the acute joint swelling often accompanying serum sickness after injection of anti-toxin, but that, instead of being an anaphylactic reaction to the injection of the foreign protein, it is the allergic reaction to toxin developed at the site of the focal infection. While little has been done to tie acute rheumatism up to the allergies, some very interesting results have been obtained in chronic arthritis.

As far back as 1924 Turnbull¹³ of Boston reported a series of cases of chronic arthritis in which definite food sensitizations were discovered, and by regulating the diet accordingly the cases all were markedly improved or entirely cured.

Freiberg¹⁴ (1929) reported an experimental study in which he produced arthritis in rabbits by repeated injections of bacterial filtrates and the following year some clinical observations bearing out the theory that at least some cases of chronic arthritis were allergic reactions to bacterial toxins. He took cultures from all

possible sources of focal infections, isolated the various bacteria, and made individual autogenous vaccines from each organism found and then did endermal tests on the patient with each vaccine. Those which reacted were then combined in the proper proportion and the patient was given desensitizing doses of this combined vaccine beginning with minute doses. Of thirteen cases he reported seven complete cures, in one of which the disease was of fourteen years standing, four improvements, and only two failures. I have used a modification of Freiberg's method on one boy who had been bed-ridden for a year with chronic arthritis. This past summer he has been playing baseball and running as well as the other boys. It is hardly to be expected when an arthritis is so long-standing that there are marked bony changes that much can be done for them. If, however, these cases can be investigated early, the cause discovered, and the patient desensitized by carefully regulated inoculations, it is probable that many of these patients may be saved from becoming chronic cripples.

I am not trying to give the impression that all diseases of mankind are allergic, and that by scratching the arm we can gain information which will cure all illnesses. I do wish, however, to leave the thought with you that the allergic reaction can do more than cause asthma, eczema, hay fever, and urticaria. It can affect any organ in the body. When you have a disease process of which you do not know the etiology and for which you have been able to do nothing therapeutically of lasting benefit, just stop and think. Can this be allergic?—and if you think it can, find out if it is!

In determining whether a particular case is allergic we have several distinct aids. A careful family history is of the greatest value. The power to become allergically sensitized is hereditary and a family history of other allergic diseases in ancestors and collateral relatives gives important information. A thorough personal history is equally important. Has the individual patient suffered from eczema in childhood, asthma, hay fever, hives or migraine? Are his attacks seasonal and periodic or do they come on in especial localities or under particular con-

ditions? Remember that a person who has one allergic manifestation is very apt to have others. Have a blood examination made and note carefully the proportion of eosinophiles. Have nasal secretions examined for the same cells. Eosinophilia is a strong evidence of allergy.

A new aid recently described is the leukopenic index.¹⁶ It has recently been shown that if a patient ingests a food to which he is allergic, instead of the expected digestive leukocytosis, repeated leukocyte counts will show a marked drop in the white count lasting for one to two hours.

If from any of the above you are led to suspect that your case is allergic, turn your patient over to an allergist. Unless you are very familiar with the technique of an allergic study, do not attempt it yourself. The science of allergy does not consist in renting a test set from a druggist and making a few scratches on the arm. The true allergist knows how much faith to put in the tests. From long experience he is able to interpret his results. The tests are not the whole story. The best they can do is to give us a hint. Following these hints, careful dietary and environmental regulations must be prescribed, and the results properly explained. Cultures must be taken, vaccines made, and tests made with these. The dosage of therapeutic inoculation must be checked by endermal testing and the proper dose determined. Environments, habits, occupation, even friends and neighbors must be considered in solving each case. Time, patience, and something of the detective instinct are required if one would be a successful allergist.

Whatever you do, do not think of the new science of allergy as a passing fad. It is a branch of medicine which touches practically every one of our specialties. Internist, neurologist, ophthalmologist, rhinologist, dermatologist are all daily, whether they appreciate it or not, treating cases of allergy and unless they recognize them as such their treatment is futile. Seeking the cooperation of the allergist just as you do of the roentgenologist in cases of doubtful diagnosis and unavailing therapeutics will add much to your reputation as a physician, and to the comfort and health of some of your most troublesome patients.

BIRTH CONTROL LAWS REINTERPRETED

On December 7, 1936, the United States Circuit Court of Appeals of the Second Circuit handed down a unanimous decision of major importance to physicians

The test case in question dealt with the legality of the importation of contraceptives from abroad, and, specifically, with the importation of a package of Japanese pessaries sent to Dr Hannah M Stone, a New York City gynecologist, for research purposes. The Customs authorities refused to admit this package on the basis of the Comstock law of 1873

Last February this case was brought before Judge Grover Moscowitz of the District Court who directed that the package of contraceptives be surrendered to Dr Stone since they were intended for legitimate medical use and the statute in question applied only to contraceptives for illegitimate use. The case was appealed by the government to the higher court whose decision proved even more sweeping than that of Judge Moscowitz. This decision when added to a previous ruling of the same court relating to the use of the United States mails (the Youngs Case in 1930) fully defines the physician's rights in this matter. The judges stated

It is true that in 1873, when the Comstock Act was passed, information now available as to the evils resulting in many cases from conception was most limited. We are satisfied that this statute, as well as all the acts we have referred to, embraced only such articles as Congress would have denounced as immoral if it had understood all the conditions under which they were to be used. Its design, in our opinion, was not to prevent the importation sale or carriage by mail of things which might intelligently be employed by conscientious and com-

petent physicians for the purpose of saving life or promoting the well being of their patients

The Court further pointed out that the Comstock Bill, as originally introduced in the Senate, contained the words "except on a prescription of a physician in good standing, given in good faith," but that those words were omitted from the bill as it was ultimately passed. "The remarks when the bill was up for passage in final form, indicate that the scope of the measure was not well understood and that the language used was to be left largely for future interpretation," the judges held

Mr Morris Ernst, chief of the defense counsel, pointed out that the Circuit Court's decision "means the end of birth control laws" and that it makes unnecessary any attempt for federal legislation regarding the rights of the medical profession in the prescription of contraceptives

The last vestige of the illegality of medically-prescribed contraception has been removed

In commenting upon this decision, Dr Eric M Matsner, Executive Secretary, National Medical Council on Birth Control, states

This decision paves the way for the increase in the number of contraceptive services in the outpatient department of all American hospitals of which at the present time there are only sixty-five. This legal interpretation brings a dual responsibility to the medical profession in the standardization and improvement of contraceptive materials and in making these available to all classes of society. If the medical profession is to control the widespread use of contraceptives it is essential that further research be undertaken by recognized medical institutions and that more adequate instruction be given in medical schools

THERAPY OF ACNE VULGARIS WITH HORMONE PREPARATIONS

THEODORE ROSENTHAL, M D, *New York City*

From the Department of Dermatology, Vanderbilt Clinic, College of Physicians and Surgeons, Columbia University

Historical

Acne does not appear to have been recognized by the oldest Greek physicians Galen, however, and Aetius (542) were acquainted with it. According to Greenhill,¹ the word should really be acme, from the Greek ἀκμή and the error in mistaking the m for n arose with Aetius, who thought that the disease occurred at the acme of the system. With these exceptions there is scarcely a reference to acne to be found in ancient or mediaeval medical literature. Not even the works of Mercurialis, or Haffenreffer, especially devoted to the subject of cutaneous diseases, make the slightest mention of it. It was not until the sixteenth century that it was again noted by Gorraeus (1578) who said "Acne is a small hard papule on the face, called by the Greeks ἰσθός, by the Latins varus."² Willan and Bateman in 1817 divided it into acne simplex, punctata, indurata, and rosacea. Erasmus Wilson in 1842 gave the name acne vulgaris to the entity that we know today, and separated it from acne rosacea.

Incidence

Acne is undoubtedly the most common skin disease of the second and third decades of life. It is estimated³ that acne patients constitute about 85 per cent of all cases seen in dermatologic practice. Bloch's⁴ summaries of the results of the examination of 4191 children between the ages of six to nineteen years, of both sexes, show that if one considers the comedo the essential lesion of acne, a few such lesions occur in an amazingly high percentage, sixty-four per cent in this series. The percentage of individuals suffering from acne increases with age, and reaches its maximum in the seventeenth

year for girls, and the eighteenth year for boys, only 34 per cent of girls in that group, and 06 per cent of boys were entirely free from the eruption.

On the basis then of the above figures alone, it would seem that the development of a few acne lesions at the age of puberty is physiologically normal. It is only when the lesions are unusually numerous, severe or persistent that we can consider acne a disease.

Etiology and Review of the Literature

Many attempts have been made to approach the problem of the etiology of acne chemically, metabolically, and by histological and bacteriological methods, with however, little success. Unna,⁵ in 1893, first described a microbacillus, termed acne bacillus, Sabouraud⁶ regarded acne as a local infectious disease of the skin based on a primary seborrhea, Gilchrist⁷ and later Ketron⁸ laid stress on the Bacillus Acnes, Whitfield⁹ emphasized the importance of gastrointestinal disturbances.

On clinical grounds, it has long been suspected that acne vulgaris is caused by some endocrine disturbance, presumably by disturbance of the gonads, and many observers have commented on it. Thus Hollander¹⁰ was impressed with the correctness of the conception that the underlying etiologic factor in acne is somewhere in the domain of the endocrine glands, probably the gonads. According to Schamberg,¹¹ when the phenomenon of the relapse during menstruation in persons with acne is considered in conjunction with the initial onset of acne at the approach of puberty, the inference appears to be justified that an internal secretion from the sex glands plays an important role. Darier¹² stated that localized acne

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 29, 1936

of the chin in young women is supposed almost certainly, to indicate utero-ovarian trouble

Cunningham and Luntsford¹³ conducted an interesting investigation among women college students, comparing 2974 girls with acne, with 3185 who did not have acne as controls. No difference was found in respect to the incidence of common disorders, such as constipation, incidence of colds, state of nutrition as expressed by weight, or conditions of the nose and throat, to which a contributory influence on acne is usually ascribed. No relationship between the presence or absence of acne in the fifteen to thirty-four year age group, and such menstrual characteristics as age of beginning, duration, irregularity in interval, amount of pain and flow was demonstrated, thyroid enlargements were found to be associated with a slight increase in acne incidence. In connection with this last finding, it is of interest to note the possibility expressed by Sulzberger¹⁴ and his coworkers, that increased thyroid activity, frequently coincidental with increased gonad activity and leading to increase in circulating thyroxin (the iodine-containing hormone) might explain acne vulgaris as essentially of the same nature as a very chronic iodide acne. Attempts to prove this experimentally by means of thyroxin patch tests did not, however, lend strength to this possibility.

The work of Stokes and King,¹⁵ in demonstrating that there is a familial and heritable element in predisposition to acne vulgaris is significant, and important in prognosis and treatment.

The late Bruno Bloch⁴ called acne, among other diseases, a dyshormonal dermatosis. He noted the fact that eunuchs are said to be immune from acne, and that there have been pathologic cases in which acne appeared in the first years of life when (owing to supra-renal tumor) sexual maturity was precociously developed. In a series of interesting tables and graphs showing the correlation of acne, on one hand, and the commencement of the menses and the appearance of pubic and axillary hair, on the other, he demonstrated clearly that in any age group those sexually developed show a higher percentage of acne than those not sexually developed.

It was Bloch's opinion that acne in its first phase is a consequence of the physiological function of the sex glands, analogous to that which we in general assume for the development of the normal secondary sexual features, such as the formation of terminal hair. The degree of their formation is undoubtedly different. This may be dependent on the fact that the production of sex hormone is varied in strength in each individual, or (and this seems more likely) that the follicular apparatus of the skin (the receptor mechanism) is individually different in its sensibility to this hormone (as for example the type of beard varies in different men). As a result we are faced by the fact that in acne the normal physiological action of a ductless gland—the sex gland—in the skin leads thru transition stages to a final effect which is pathological—a real lesion of the skin, namely acne.

Clinical Investigations

A large amount of circumstantial evidence, clinical intuition, and conjecture implicating the sex glands in the etiology of acne has thus been accumulated, but until recently there was no means of demonstrating exactly the variations from the normal of the function of any sex gland. The newer knowledge of ovarian function, however, has provided a fairly precise method for determining the excretion of estrogenic substance in blood and urine, both qualitatively and quantitatively.

This was initiated by the studies of Stockard and Papanicolaou,¹⁶ Evans and Long,¹⁷ and Allen,¹⁸ and depends on the fact that synchronously with the cyclical changes that take place in the ovaries, there occurs a cyclical change in the uterus and vagina of the animals used, and that the vaginal secretions partake of this change. The estrogenic substance is concentrated by lipid extraction of the blood or urine. It is unnecessary here to go into detail regarding the principles and technic of its isolation and recognition. In our work the method described by Kurzrok and Ratner¹⁹ was used for extracting the hormone from the urine, and that of Frank and Goldberger²⁰ for extraction from the blood. The vaginal spread of the castrated rat is used as indicator.

For the sake of completeness, although the author has had no experience with it, some mention will be made of the testis hormone. This was recognized by McGee²¹ in 1927 in lipid extracts of the testes. The test for the testis hormone is not as clearly defined, and is slower than that for estrogenic substance in the female, and is accomplished by means of the capon test (comb, wattles, and spurs).

It is important, at this juncture, to emphasize the discovery by Smith²² and shortly after by Zondek and Asheim²³ that both ovary and testis remain dormant unless stimulated by the secretion of the adenohypophysis (anterior pituitary or prepituitary gland) and that this gonadotropic factor activates alike the gonads of both sexes.

It was thought that evidence of normality of ovarian function would be indicated by a study of the excretion of estrogenic substance in the urine and blood of patients with acne. Kurzrok's²⁴ studies have shown that normal women between the ages of sex maturity and the menopause excrete from ten to twenty rat units of estrogenic substance per liter of urine throughout the menstrual cycle.

The urines of thirty-four young women who applied to the Vanderbilt Clinic for treatment of acne were examined. The age range was eleven to thirty-three years, twenty-one being under twenty years of age.

The results were as follows:

Strongly positive reaction (10-20 rat units)	No of patients 6
Slightly positive (4 rat units)	82% { 1
Negative reaction	27

In the blood, the work of Frank and his associates²⁵ tends to show that in the normal fertile menstruating woman the concentration of estrogenic substance undergoes regular cyclic variations, and also that the renal permeability of these substances varies in the individual. In view of these possibilities, it seemed desirable to repeat the above observations, estimating premenstrual values for estrogenic substance in the blood of patients with acne.

In normal fertile menstruating women, Frank and Goldberger found one mouse unit of estrogenic substance in forty cubic centimeters of blood taken from the tenth

to the third day premenstrually in forty-four per cent of their patients, while from the third to the first day premenstrually at least one mouse unit was present in the blood of one hundred per cent of the patients. (Average for the entire period seventy-two per cent.) Neustaedter²⁶ found estrogenic substance in the blood of seventy-five per cent of his patients in a similar interval, Mazer and Goldstem²⁷ found the percentage slightly higher in their series (eighty-five per cent).

With these figures representing average norms, we may compare them with the findings in normal menstruating women with acne. Twenty-nine consecutive patients with acne with normal menstrual histories were examined. In none of the patients studied were any other acne-producing factors, dietetic or chemical, detected. Their ages ranged from eleven and one-half years to thirty-four years, and the menstrual interval ranged from twenty-one to thirty-one days.

Forty cubic centimeters of venous blood obtained within seven days of menstruation was assayed for estrogenic substance by the method of Frank and Goldberger. The results were as follows:

Strongly positive reaction (1 mouse unit)	No of patients 2
Weakly positive (less than one mouse unit)	93% { 16
Negative reaction	11

Results of Treatment

Van Studdiford²⁸ treated a number of female patients with acne with a variety of endocrine products, including desiccated ovarian extract, and orchic extract. More recently fifteen patients were treated with estrogenic substance, three doses being given by injection on alternate days one week premenstrually. Of these patients, eleven improved. Sixteen patients in another series were treated with a preparation of gonadotropic substance postmenstrually, as a stimulative measure, followed by the injection of estrogenic substance premenstrually, as a substitutional measure. Eight of the patients treated in this manner showed improvement.

Michael,²⁹ working in cooperation with gynecologists in order to employ the newer endocrine products in the most

suitable manner, treated twenty-six acne patients with hormone therapy. The therapeutic results were poor, and discouraging so far as the influence of the hormone treatment on the acne was concerned.

Lawrence and Feigenbaum³⁰ treated six males and eight females with pregnancy urine extract, with results sufficiently satisfactory to warrant further study. In a subsequent report, Lawrence³¹ treated a series of thirty patients in the same manner, ten were regarded as cured, as they had had no relapse two months after treatment has ceased, while eleven were definitely improved.

The patients in my series number thirty-eight females and two males, practically all of whom were followed for almost two years. The ages of the female patients ranged from thirteen to thirty-three years, the average age being nineteen and eight-tenths. Physical examination, apart from the presence of acne vulgaris, was essentially negative in all, except for two patients who had pulmonary tuberculosis in arrested stages. One patient showed a basal metabolism rate of plus thirty-five per cent, although there were no clinical signs of hyperthyroidism. Seven of the patients were married.

An analysis of the menstrual histories of the patients studied failed to reveal any relation between the acne and any particular menstrual characteristic. A number of the patients reported premenstrual aggravation of the eruption, while a few thought that it was better at that time.

Treatment consisted of five injections of one cubic centimeter each, of a preparation of estrogenic substance (fifty rat units) given at daily intervals, followed by the same number and dosage of a pregnancy urine preparation (containing one hundred rat units to each cubic centimeter) instituted postmenstrually. This amount of treatment was termed one course. After the next period, a similar course of treatment was administered. During this time no local applications or treatments were prescribed.

The two male patients, aged seventeen and eighteen years, were given one cubic centimeter of pregnancy urine extract three times weekly for several weeks, one

made a speedy and complete recovery, while the other showed no improvement.

The results of treatment of the female patients are as follows:

	No of patients	Average no of courses per pt
Definitely improved	13	2.3
Slightly improved	10	1.8
No improvement	15	1.4

It is evident that the total amount of treatment administered bears a definite relation to the end result, as the patients who improved received almost twice as much as those who did not (2.3 courses compared with 1.4).

In connection with this type of therapy, it is pertinent to call attention to the possible ill effects attending prolonged treatment with estrogenic substances. Kunde et al³² in 1930 showed that continued high dosage of estrogenic substances has a distinctly sclerosing effect on the ovaries. Numerous reports have also appeared relating to the carcinogenic properties of estrogenic substances, one observer³³ states that mammary cancer developed in male mice following treatment with these substances, while others³⁴ saw atypical growths, resembling cancerous changes in the uterine cervix of monkeys after prolonged treatment. Recent biochemical studies of Dodds,³⁵ and Marran,³⁶ among others, have demonstrated the close chemical and biological relationships between carcinogenic compounds, estrogenic substances, and Vitamin D, or calciferol.

Comment

The treatment of acne is still a problem, mainly as a result of uncertainty as to its cause, roentgen therapy, formerly regarded as a specific, has not proven completely satisfactory in all cases. It is believed that on the basis of the foregoing investigations one may assume that a definite relationship exists between the estrogenic hormone and acne, and that a deficient secretion of this hormone may prove to be the direct or indirect factor in the causation of one type of acne. While it is known that the anterior pituitary gland governs or regulates gonadal activity, no information is available as to the apparent dysfunction, if any, in the link between it and the ovary. In this con-

nection a possible, although very remote explanation of part of the improvement following roentgen irradiation may be attempted. It is conceivable, that, in the course of routine filtered roentgen therapy for acne, the pituitary gland is affected by the irradiation administered, and in consequence induces a normal gonadal response.³⁷

The evidence is strong then, that one type of acne is caused by disturbance in the sex endocrines. Just what that disturbance is, or how it acts, is not clear. Endocrine therapy for acne is not yet reliable because we do not know the best preparations to use, or how best to administer them. At the same time, in addition to any so-called specific treatment, an appreciation of the secondary factors involved in the management of any acne patient is very important, these have been very clearly outlined by Wise and Sulzberger,³⁸ and need no re-emphasis here.

Conclusions

Estimation of estrogenic substance in the urine and in the blood in two independent series of females with acne yielded

parallel results (1) Eighty-two per cent of patients showed absence or subnormal quantity in the urine, (2) Ninety three per cent of patients showed absence or subnormal quantity in the blood.

This leads to the belief that associated with acne there is abnormality of formation or of utilization of the sex hormone. The exact nature of this aberration and the direction it takes are unknown. It is as yet undetermined whether lack of estrogenic substance or some other basic fault is the cause of acne.

Treatment of these patients with preparations of estrogenic substance and gonadotropic substance produced some favorable results (sixty per cent improvement).

Prolonged treatment with estrogenic substances is not without danger, sclerosis of the ovaries, and carcinogenesis have been reported.

The basic principles underlying the general management of patients with acne must not be overlooked, regardless of what specific therapy may be employed.

ULCERATIVE COLITIS

Bacteriological Aspects

WILLIAM Z FRADKIN, M D, Brooklyn

From the Department of Medicine, Division of Gastroenterology, and the Department of Laboratories, Division of Bacteriology, Jewish Hospital

The early recognition of the etiology in a case of ulcerative colitis is extremely important. The appalling morbidity of this disease could be greatly reduced if every physician would take the stand that an ulcerative colitis is amebic or bacterial in origin, unless proven otherwise. Furthermore, the policy of prescribing antiseptics and opiates for a bloody diarrhea, before a thorough bacteriological investigation, is a pernicious one because the etiological study is made very difficult, if not impossible. The prognosis also becomes progressively worse. The vicious chain of events such as diarrhea, loss of blood, anemia, dietary reduction, avitaminosis, loss of weight, weakness, chronicity, and psychoneurotic

The author wishes to acknowledge the technical assistance of M. Mollov, M.A. and E. Hendler, A.B.

changes, soon lead to a state which is difficult to combat even when the causative agent is finally detected and specific therapy instituted.

Progress in the handling of this problem has been aided by the invention of new instruments, improvement in cultural technic, and added accurate serologic tests. In April 1934, the writer described a Sigmoid Aspirator¹ for obtaining fresh sterile saline suspensions of rectosigmoidal contents from which stool examinations could be made more accurately. In July of the same year, a Simple Sigmoidoscopic Aspirator² was described by means of which material for examination can be obtained under sterile precautions through the Sigmoidoscope directly from the ulcers in the rectum or sigmoid. These instruments (Fig 1 and 2) have been largely respon-

paratyphoid B bacillus in one case, and a pure culture of nonhemolytic streptococci in one case. The diplostreptococcus was not considered of primary etiologic importance when found fairly frequently associated with a bacillary or amebic infection. For this reason, only three cases are classified as primary infections with the diplostreptococcus of Bargaen. Twelve cases showed positive dysentery agglutination tests. In eleven of these, dysentery phages were present. Only dysentery phage was found in two cases. Two cases were repeatedly negative serologically and bacteriologically. In other words, thirty-two of the thirty-six patients revealed specific infections by culture or serology (Table II). There were six cases of non-ulcerative colitis in which dysentery bacilli were isolated on culture, but which were not included in this report.

Comment

Some clinicians believe that the *Entameba histolytica*, or the dysentery bacilli,

even when found, are of questionable etiologic significance in ulcerative colitis. The excellent results with antamebic therapy easily disproves this belief as far as the *Entameba histolytica* is concerned. Whether this is true regarding the dysentery organisms is still a moot question. However, given a patient with a mucopurulent bloody diarrhea associated with tenesmus and fever, the finding of dysentery bacilli in the discharges appears to be of definite diagnostic value. Similarly, the finding of the diplostreptococcus of Bargaen, or the paratyphoid bacillus in practically pure culture, directly from the ulcerative lesion should influence the conduct of the case by the clinician.

Since experience has shown that it is difficult to isolate dysentery bacilli in the chronic stage of the disease, agglutination tests were undertaken to detect these cases. The interpretation of the results looms large in the eyes of the critical. When the technical work is properly and sufficiently carried out with controls and

Methods of Study

Success in isolating the offending organism depends entirely upon the strict technic used, and the number of specimens examined. A minimum of seventy-two hours is required to determine whether or not a dysentery bacillus is present in the aspirated specimen. Therefore, to rush the bacteriologist for a report only invites error.

The routine procedure consists of the following:

No medication is permitted for at least three days prior to examination, and roentgenologic studies should not be attempted during this period. The patient may be given a saline irrigation early on the morning of examination.

The use of a soap suds enema should be guarded against as the soap interferes with culturing and isolation of pathogenic organisms. It also inhibits the motility of amebae when present, and renders their recognition more difficult.

In adults, the purulent bloody exudate is aspirated directly from the base of the ulcer under direct vision through the Sigmoidoscope. After the specimen is obtained it is immediately examined at the bedside for the *Entameba histolytica*, using a warmstage microscope. Cultures are made on blood agar, on five or six Endoplates, and in glucose broth. Plain broth tubes are also inoculated for the detection of bacteriophage. At the same time, smears are made for study with acid-fast and Gram stains. It is essential that all culturing be done at the bedside. The predominating organism of the smear is noted, and the result is compared with the cultural findings. (At present we use in addition to Endo's media, plates of MacConkey's bile salt agar and brilliant-green agar.) About ten c.c. of blood is collected for dysentery agglutination tests. If the findings are negative at the end of seventy-two hours, the procedure is repeated until three to five negatives are obtained before the case can be classed as one of nonspecific ulcerative colitis. Although this investigation is time-consuming, the seriousness of the disease justifies it. Recently, a patient was sigmoidoscoped five times before the aspirated specimens finally revealed the Flexner dysentery bacillus on culture. In most cases, two or more sigmoidoscopic examinations with aspiration of

material were necessary before positive findings were obtained.

If the patient is an infant, a saline suspension is aspirated by means of a catheter inserted into the rectum. The free end of the catheter is attached to a sterile ten c.c. syringe containing warm sterile saline solution. The saline is injected and aspirated repeatedly until a satisfactory suspension is obtained. With an older child the same routine can be followed, although it is preferable to aspirate directly from the lesion through a child-size sigmoidoscope.

Examination of stool specimens alone are unreliable. A patient (M F) fifty-five years of age was seen in the dispensary complaining of a bloody diarrhea, intermittently, for a period of twenty-five years. Stool specimens were sent to the laboratory on numerous occasions with negative bacteriological reports. Finally, a warmstage microscopic examination of exudate aspirated direct from the ulcerations through the sigmoidoscope revealed fields swarming with actively motile amebae containing ingested red blood cells. Antamebic therapy promptly cured this patient.

Similarly, a sixteen year old girl (M S) with chronic ulcerative colitis gave a five year history of illness with many admissions to hospitals, but at no time was anything of significance found in her stools. Bedside culturing of aspirated exudate direct from the lesions revealed many colonies of the Flexner dysentery organism.

Carriers of amebae or dysentery bacilli are best followed up by culturing specimens aspirated direct from the inflamed mucous membrane, rather than by studying cultures made from the stool. An experience occurred recently where stool cultures of a convalescent were repeatedly negative, while culture of one aspirated specimen yielded colonies of dysentery bacilli.

Results of Study

From May 1 to December 1, 1935, during a period of seven months, thirty-six cases of ulcerative colitis were studied in the above manner (Table I). Most of these had been diagnosed as nonspecific from the sigmoidoscopic appearance, or from a negative stool examination on one or two occasions. Nevertheless, dysentery bacilli were isolated from aspirated specimens in ten cases, including a double infection with the *Entameba histolytica* in one case, the *Entameba histolytica* in five cases, the *diplostreptococcus* of Bagen in practically pure culture in three cases,

PNEUMONIC TYPE OF BACILLARY DYSENTERY

JOSEPH FELSEN, M D, *New York City*

In a previous communication¹ it was stated that bacillary dysentery was a systemic disease due to *B dysenteriae* and its toxins in which the intestinal lesions represented only part of a more generalized pathology. It was further stated that the clinical manifestations arising from disordered function in other organs sometimes overshadowed the classical dysenteric symptoms attributable to the intestinal tract. The meningitic, appendicular, and agranulocytoid types have been described.^{2,4} Several additional examples of the protean character of bacillary dysentery have recently been noted in the New York City area in which the disease simulated lobar pneumonia at the onset.

The association of upper respiratory symptoms with mesenteric lymphadenitis in acute bacillary dysentery has previously been encountered chiefly in children, particularly in the Sonne-Duval type.⁵ The present form has thus far been noted only in adults and all have been of the Flexner type. During the incubation period of twenty-four to forty-eight hours the patient complains of malaise, headache, anorexia, nausea, and indefinite muscle pains or "body aches." This is followed by a chill and sharp rise in temperature which may reach 105 or 106°F. There is marked prostration, a rapid pulse, and a short non-productive cough. The face is flushed, but there appears to be no respiratory difficulty or pain referable to the chest. Upon auscultation some fine moist rales are heard which persist after coughing. The cough is very transitory, but a roentgenogram of the chest of one patient taken during the first twenty-four hours showed a definite localized area of increased density, approximately ten cm in diameter, suggestive of a beginning pneumonic consolidation. Subsequent pictures, however, revealed this to be an abortive process with complete subsidence of the pathology in about forty-eight hours.

There is nothing as yet to indicate the

true nature of the infection, although the clinical impression is that of acute lobar pneumonia. Within twenty-four hours, however, the patient complains of abdominal discomfort or cramps which is soon followed by frequent blood-tinged, mucoid bowel movements. These may amount to as many as thirty during twenty-four hours. Frequently there is marked tenesmus and the bowel movement consists wholly of blood-flecked mucus. In one instance this material contained *B dysenteriae* Flexner in pure culture. With the onset of diarrhea the temperature may recede slightly.

The clinical course is now typical of bacillary dysentery with its dehydrating and exhausting watery bowel movements and almost continuous cramps. Spastic ileum and sigmoid are readily palpated and, where the abdominal wall is thin, enlarged mesenteric or mesocolic nodes may be felt at or near the ileocecal angle. Sigmoidoscopic examination on successive days reveals the characteristic three stage pathology of the intestinal lesions, namely (1) Punctate follicular hyperplasia (of the solitary acuminate lymph nodules), (2) Punctate follicular necrosis with discrete ulceration, (3) Confluent ulceration with geographic or serpiginous mucosal denudation. The mild cases often do not progress beyond the second stage. The average duration of the disease is seven to ten days by which time the temperature has gradually receded to normal, the intestinal movements have markedly subsided, and the general mental and physical state have greatly improved. There then follows a period of obstinate constipation which represents Nature's effort at splinting the bowel to favor healing. Any patient whose intestinal lesions have not healed by the end of the third week should be regarded as a potential case of chronic distal ileitis or ulcerative colitis. Prompt treatment and persistent follow-up in the early stage of chronic dysentery are essential for the ultimate cure of this most obstinate disease. In this connection

positive sera, and using agglutinable organisms, the findings are of significance. A definite agglutination with Shiga or Sonne dysentery strains in dilutions of 1:40 or higher is considered diagnostic. With the Flexner, Hiss, and Mt. Desert strains, an agglutination of 1:160 is required for a positive diagnosis. Furthermore, repeated agglutination tests showing a definite rise in the titer of the patient's serum has been considered of even greater value in establishing the final diagnosis.

The presence, or absence, of dysentery bacteriophage in the rectal discharges of a patient suffering with ulcerative colitis, is of interest purely from a confirmatory point of view. Felsen³ (New York) and Feemster⁴ (Boston) have shown that valuable evidence may be obtained by studying the stool for the presence of dysentery phage. Friedemann⁵ in 1921, felt that the lytic effect of the phage might be responsible for the difficulty in recovering the dysentery organisms. In this series, two patients showed dysentery bacilli and dysentery phages at the same time.

Summary and Conclusions

1. An effort should be made to deter-

mine the etiology of any case of ulcerative colitis as early as possible.

2. Material for bacteriologic study should preferably be obtained by aspirating exudate direct from the lesion through the sigmoidoscope.

3. Specimens must be examined and cultured repeatedly if previous findings are negative.

4. No medication should be given for at least seventy-two hours prior to cultural studies.

5. Intensive investigation of thirty-six cases of ulcerative colitis, acute and chronic, revealed the *Entamoeba histolytica* and the dysentery bacilli as the most common etiologic agents. Next in frequency, is the *diplostreptococcus* of Bargen.

6. Progress in the etiology of ulcerative colitis will depend upon the close cooperation between the clinician and the laboratory staff.

"PACIFIC COAST ABORTION RING"

The abortion industry has reached a point where a "tristate illegal operations syndicate" was recently exposed on the Pacific Coast, doing business in Washington, Oregon, and California. The principals were haled before Judge Arthur Crum, of the Superior Court for the County of Los Angeles, the trial was short, sharp and decisive, and eleven of them were found guilty and promptly sent to the penitentiary.

We are told in *California and Western Medicine* that the "syndicate" secured, among other activities, the cooperation of a former enforcement officer of the California Board of Medical Examiners, now for the time being committed to jail by the Court because of his efforts to intimidate witnesses for the State.

The leaders of the syndicate, indeed be-

came so brazen that they even gave defiance to the California Examining Board, in the belief that the safeguards and loopholes, which their legal counselors had advised them to use in their operations, would be sufficient to protect them from attack by the State's authorities. The syndicate's plan of operation was originally conceived by a lay citizen of the State of Washington, a lumberman who went so far as to create a "Medical Acceptance Corporation" (after the style of automobile financing agencies), so that payments, with rates of interest appropriate under the circumstances, might be secured from some of the patients. So-called clinics were established in about ten of the Coast cities. The money profits are stated to have approximated an annual sum of something like one million dollars!

POSTOPERATIVE SEDATION

R FRANKLIN CARTER, M D , *New York City* and G G BROAD, M D *Syracuse*
Department of Surgery, New York Post-Graduate Medical School and Hospital

This study was undertaken with the purpose of determining what value there may be in systematized postoperative sedation of surgical patients, with the employment of a routine drug treatment. Barbituric acid derivatives, as examples of well-known and widely-used drugs, were the sedatives under consideration.

The material studied comprised one hundred cases of gynecological surgery. The average age of the patients was thirty-four. Three of them had symptoms of cardiac dysfunction of mild degree. Otherwise they were patients of normal health except for their gynecological conditions.

There were 114 operations on these patients, sixty-seven of which were done through abdominal incisions, nine were drained, and in two the combined abdomino-perineal approach was used. There were fourteen operations for vaginal repair, ten for cervical repair, and twenty-three cases which included dilatation and curettage.

In the hundred cases studied, fifty-nine of them were given barbituric acid derivatives and the dosages were computed as comparable to that of phenobarbital, which was the single derivative most frequently used.

Preliminary Narcotics and Anesthetics

Morphine grain 1/6 and atropine grain 1/150 were used as a preliminary narcotic in seventy-two cases, of which sixty-nine were for gas-ether anesthetics, two for gas-oxygen, and one for ethylene. Morphine grain 1/4 was used in eight cases, six of them with spinal anesthetics, and two with gas-ether. Morphine grain 1/6 was used ten times, five for gas-ether, two for gas-oxygen, and three for spinal anesthetics. No preliminary narcotic was used in ten instances, of which seven had gas-ether, and one each had gas-oxygen, ether, and local anesthetics.

Postoperative Narcotics

The routine postoperative care included morphine for the first twenty-four or forty-eight hours. By way of indicating that this series of cases had what may be regarded as usual doses the following data were revealed:

8 cases had no morphine following the operation
7 cases had morphine not exceeding grain 1/4 as a total
21 cases had morphine not exceeding grain 1/2 as a total
23 cases had morphine not exceeding grain 3/4 as a total
21 cases had morphine not exceeding grain 1 as a total
19 cases had morphine not exceeding grain 1 1/2 as a total
1 case had morphine not exceeding grain 2 as a total

In addition thirty-one cases had codeine, fourteen of them using more than two grains and seventeen using less than two grains.

Postoperative Sedation

As mentioned earlier, the sedative chiefly employed was phenobarbital, and when other barbiturates were used (in a small percentage of cases) comparable doses of phenobarbital were substituted, for the data. Fifty-nine cases were given phenobarbital. In contrast, forty-one received practically no postoperative medication beyond the morphine and codeine limits already described.

The phenobarbital was administered in doses of 1 1/2 grains, 1 grain, and 1/2 grain two or three times a day, starting usually on the day after operation. The higher dosages would be used at first and the lower ones then used to taper off the sedation as the patient gradually returned to normal condition.

The figures compiled from the charts of the patients showed that the average dose was 24 grains of phenobarbital per day, and the average number of days for its use was nine.

it is important to remember that acute bacillary dysentery may affect any part of the small or large intestine, but has a special predilection for the distal ileum and colon. It is at these very sites that the chronic lesions are also found (chronic distal ileitis, nonspecific granuloma, chronic ulcerative colitis).

Diagnosis of the pneumonic form of bacillary dysentery is based upon the clinical symptomatology already outlined, positive fecal culture during the first week and a rising agglutination titer and bacteriophage after the first week. The time factor as stated is a general one and subject to individual variations. Abortive forms of the disease may last only a few days. The importance of early recognition of this unusual form of bacillary dysentery need hardly be stressed from the standpoint of contact infection. Unless prompt isolation is effected early in the disease many secondary cases may arise since the intestinal contents are often teeming with specific organisms during the first week.

Therapy varies with the stage at which the disease is encountered. Castor oil should be used early in imitation of Nature's attempt to eliminate the organisms and toxins and to prevent their reabsorption through ulcerated areas. Antidysentery serum is most effective during the first twenty-four to forty-eight hours. Bacillary dysentery is usually a self-limited disease with a tendency to spontaneous recovery in about ninety per cent of the cases within ten days. The other ten per cent develop the chronic lesions above noted, these figures being based upon the follow-up studies of the Jersey City epi-

demic⁶ due to the Flexner organism. For dehydration and toxemia, liberal amounts of fluid by mouth or five per cent dextrose in normal saline by phlebotomy should be used. In chronic dysentery the use of D-C vaccine, D-C antiviral, and intestinal oxygenation is advisable.⁷

Active immunization against the primary and secondary invaders (*B dysenteriae*, *enterococcus*, *B coli*) is now being employed routinely in every case of acute dysentery as soon as the clinical condition permits. Used in conjunction with preventive therapy (i.e. public health measures directed against acute dysentery) it is expected to bring about a lowered incidence or perhaps complete eradication of the chronic intractable forms of the disease.

Summary

The pneumonic form of bacillary dysentery is characterized by its abrupt onset with chill, marked hyperpyrexia, and pulmonary manifestations. These are very transitory and are succeeded within twenty-four hours by the intestinal symptoms characteristic of dysentery. The protean nature of bacillary dysentery is noted and the essentials of diagnosis and therapy outlined.

The division of psychiatry of the department of hospitals, city of New York, held an interesting meeting on December 16, at the Bellevue Hospital, New York City.

On the program were Dr S S Goldwater, chairman, commissioner, department of hospitals, Dr Samuel W Hamilton, national committee for mental hygiene, "The Problem of Psychiatric Care in New York City," Mr Stanley P Davies, general director, charity organization society "Psychiatry from the Standpoint of Social

Agencies," Dr Karl M Bowman, director, division of psychiatry, "Activities of the Division." Then followed five-minute discussions by Hon A H MacCormack, commissioner, department of correction, Dr Frederick W Parsons, commissioner, state department of mental hygiene, Dr Foster Kennedy, Mr Douglas P Falconer, general secretary, Brooklyn bureau of charities, and Hon Cornelius F Collins, justice, court of general sessions.

POSITION OF THE URETERS AND TRIGONE IN PROLAPSUS UTERI

MARY LEE EDWARD, B A, M D, F A C S, *New York City*
Surgical Department, New York Infirmary for Women and Children

In gynecology one of the largest groups during or past middle age consists of cases of prolapsus uteri where the ligaments and fasciae have been torn or relaxed allowing the pelvic organs to descend. In these cases the vaginal wall may present beyond the introitus, the cervix may appear or the uterus itself may be palpable outside the vulva. The operation of choice¹ may be anterior and posterior colporrhaphy, posterior colporrhaphy and suspension, transposition²⁻⁴ with amputation of the cervix or vaginal hysterectomy⁵. Whatever operation is chosen, the ureter and trigone are two of the most important structures in the anatomy of the region.⁶⁻¹⁰

In operating upon these patients, we should naturally expect to find the ureter in the same relations to surrounding structures as in the normal subject, i.e. passing under the uterine vessels below the base of the broad ligament lateral to where it is inserted into the cervix. It seems from our observations that this relationship may be distorted and the extent of prolapse of the trigone and the ureters is not always obvious clinically upon vaginal examination.

In Tandler and Halban's⁷⁻⁸ "Anatomie und Aetiologie der Genital Prolapse beim Weibe" they state that "the trigone runs in the greatest number of cases stretched backwards and forms a part of the anterior wall of the cystocele." The border between the abdominal portion of the bladder and the cystocele corresponds to the genital hiatus.⁹ They also state that "dilatation and hypertrophy of the ureters is almost typical. The dilatation exists mechanically through obstruction which occurs at the hernial ring as the site of constriction of the ureters." Only in those prolapses is there no hydrourer

in which the cystocele is so small that the ureter opens into the bladder above the genital hiatus." In another place, they say "often only the recessus retrouretericus, often also the trigonum and bladder fundus, finally also a part of the body of the bladder appears pulled into cystocele."

Brettauer and Rubin¹¹ state "the pull on the ureters exerted by the abnormally dependent cervix and uterus forms a constriction about the point where the post-mortem studies of Tandler and Halban and our pyelograms on the living subject show it to be." The constriction to which the prolapsed bladder is subjected at this genital rupture ring is shared by the ureters and hence result the stasis and dilatation." They believe the compression is due to the uterine vessels.

Kelly¹² says in a rare form the bladder may stay within the pelvis, in prolapsus uteri.

Philipp and Krantz¹³ in their work on prolapse of the bladder, state that the bladder in the trigonal portion is unyielding.

Our attention was first called to the importance of the position of the trigone in prolapsus uteri in July 1933. A patient (M S, aged 59) came with a complete procidentia and in addition a walnut-sized fibroid at the cervico-fundal junction, which presented outside the introitus. We expected some difficulty in operating and decided that cystoscopic examination might be of value in showing the relationship of the bladder and ureters to this tumor. This cystoscopy showed that with the uterus prolapsed the ureters were about four inches from the tenaculum on the cervix, i.e. there was relatively little prolapse of the ureters—less than one would have expected from Tandler and Halban's studies on the cadaver.

This led us to cystoscope other patients with prolapse and since then we have cystoscoped twenty-two other women

I wish to thank Dr Anne Elizabeth Kühner and Miss Margaret Bowie, R N, of the Department of Urology for their help in this work.

Postoperative Course

The postoperative course of the patients was followed and a record made to see whether those patients who received phenobarbital or its equivalent had more or less of the postoperative complaints than those who were given no routine sedatives. Those who received the phenobarbital did so in regular daily doses without specific regard to complaints.

The details of the findings may be briefly stated under the headings indicated below.

1 Distention and gas pains These complaints are judged by the amount of bowel activity impelled for their relief.

All cases with phenobarbital required an average of one cathartic or enema for one day only.

Two-thirds of the cases without phenobarbital required an average of 24 enemas for an average of two days.

2 Coughs Two cases with phenobarbital (0.3% of such cases) had sufficient coughing to be recorded on nurses' notes. Ten cases without phenobarbital (24% of such cases) had coughs for an average time of 26 days.

3 Hospitalization The abdominal cases which received phenobarbital were discharged from the hospital on an average of about the fifteenth day, whereas, those who did not receive the medication were discharged on an average of approximately the nineteenth day.

The perineal-cervical cases with and without phenobarbital were discharged on an average of the tenth and ninth days, respectively.

It should be noted that all these cases were treated by one doctor, who would be expected to use similar criteria for discharging all the patients.

Summary

One hundred gynecological cases which had been operated upon by one man were studied with the purpose of determining the value of routine postoperative sedation.

The anesthetics and pre- and postopera-

tive narcotics for the types of operations in each group were practically identical throughout the series. In the hundred cases reviewed, fifty-nine of them had been given barbiturates in routine doses, and the remaining forty-one had no regular sedation.

Distention and gas pains, as indicated by cathartics and enemas given, were more pronounced in the non-barbiturate group. Coughs were markedly more frequent in the patients without the phenobarbital. The abdominal cases with the routine sedation were discharged from the hospital on an average of four days earlier than those without the sedative routinely prescribed.

Comment

It has been said that figures may be obtained to prove anything. Unfortunately the data revealed in this study were not so convincing as the general impression which is given to an observer of this series of patients. Not only did the patients receiving the routine barbiturates seem more comfortable and less disturbed during their convalescence than those without that therapy, but happily the figures showed that the abdominal cases left the hospital four days earlier on an average, than the cases without phenobarbital.

It is the belief of the writers that the decrease in the distention and coughing was of benefit to those patients receiving barbiturates, not only in lessening their distress but being of some import in their recovery. Also, the patients' sense of comfort and peace of mind are enhanced by routine sedation.

It is worthy of note that there has been no tendency for patients to seek further sedation after the drug was stopped, either before or after discharge from the hospital.

Fig 3a Considerable prolapse of ureters and trigone and descent of urethra. Pointer rests on urethral meatus (Case 3)

Fig 3b Same case after operation

and hence the degree of prolapse of the trigone and the ureters

Seven cases are presented in which cystoscopic studies demonstrate the variation which may occur in the position of the trigone and ureters

CASE 1 FW, age sixty-six, a patient with complete prolapse since 1894, there was a descensus of the urethra, a prolapse of the ureters, and a prolapse of the bladder

toscope was put in again after being withdrawn to see that the catheters remained in position. In this way the comparison of the first and second plates showed the change of position of the ureteral meati

Fig 1a Descent of urethra and prolapse of ureters (Case 1)

Fig 1c. Lateral cystogram of same case.

Fig 1b Cystogram of same case.

Of these twenty-three patients, eleven have been operated upon by various methods and it now appears that cystoscopy may be of some aid in deciding the operative procedure, i.e. the degree of prolapse of the trigone and the ureters may be an important deciding factor in choosing the type of operation

The method followed at first was simple cystoscopy with ordinary x-ray catheters and in some cases cystogram. After we had done several cases, Dr. Anna Hubert suggested a two piece catheter with the upper x-ray portion ending at the ureteral meatus, thus marking on the x-ray the location of this meatus and hence the trigone and the position of the lower portions of the ureters.

The cystoscope was inserted as in routine cystoscopy after the prolapse had been replaced. Some of these cases showed marked fasciculation and trabeculation as well as distortion of the bladder, urinary retention, residual urine, and a membranous exudate of pus which made it difficult to find the ureters and necessitated treatment before catheterizing the ureters. When the ureteral catheters were passed, and the cystoscope withdrawn, a plate was made. The first plate was taken with the prolapse replaced. The uterus was then allowed to descend, a tenaculum placed on the cervix, and a second plate made. In some of the early cases the cystoscope was not withdrawn but it was found that it tended to support the structures, and in all later cases it was withdrawn. In some cases the cyst-

Fig 6a. Little or no descensus of ureters (Case 6)

Fig 6b. Little descensus of bladder

amination was "the urethra is held up fairly well, large cystocele, complete prolapse." Cystoscopy showed prolapse of the ureters and urethra. This case was carefully operated upon by one of the most expert members of the staff. The result with simple anterior and posterior colporrhaphy was poor. She returned with a cystocele and was given a pessary.

In this case, before operation the prolapse of the ureters and urethra was not diagnosed clinically, although it was evident upon cystoscopic examination (Fig 5).

CASE 6 D L, age forty-four. Complained that the uterus had been falling down for three months. "The womb seems to come clear down." The vaginal examination showed the cervix projecting beyond the vulva, cystocele, rectocele, fundus large, posterior.

Cystoscopy showed little descensus of the ureters, little or no descensus of the bladder. Operation: amputation of the cervix, perineorrhaphy, Gilliam suspension. The result was good (Fig 6a-b).

CASE 7 V P is shown because it is unlike any of the preceding. This patient has had two operations for prolapse and still has a very large prolapse. In this case, however, the rectocele is the more prominent part of the prolapse. The cervix is about two inches beyond the vulva but almost the whole posterior vaginal wall is prolapsed. There are a large rectocele and an entero-

cele posteriorly, anteriorly a band beneath the urethra holds firmly. Cystoscopy shows the trigone just below the pubis and the ureters in a fairly deep loop below this. Evidently all the pelvic organs but the trigone descended causing the ureter to lengthen and form a loop as the result of descent of the posterior part of the pelvic floor (Fig 7).

It appears from studies with the cystoscope upon living subjects that in pro-

Fig 7. Different type of case (Case 7)

down nearly to the tenaculum at the external os. This patient was not operated upon and the x-rays are shown merely to illustrate a type of complete prolapse of the ureters and trigone. This is what one would expect to find in all cases (Fig 1a-c).

CASE 2 I.H., age sixty-three, suffered from a laceration thirty-one years ago and

Fig 4a Before operation, no great degree of prolapse of trigone and ureters (Case 4)

Fig 4b After operation

came complaining of a mass between the legs. She had no urinary symptoms, no frequency or dribbling, and stated that the urine was "hard to come out." We found no prolapse of the urethral meatus, but a complete procidentia with prolapse of the anterior and posterior walls of the vagina.

The top of the fundus was beyond the vulva. There was a firm band immediately below the urethra across the urogenital triangle. On cystoscopy we found practically no prolapse of the ureters showing that the portion of the bladder which had been carried down was the posterior wall and not the trigone. This case is shown to illustrate the opposite type from case 1 (Fig 2a-b).

CASE 3 M.R., age fifty-eight, came complaining of dribbling of urine and a mass between the legs. She had complete prolapse of the uterus and the urethra torn away from the pubis. Cystoscopy showed pro-

Fig 5 A type of case repaired frequently by anterior and posterior colporrhaphy with poor result. Pointer rests on urethral meatus. (Case 5)

lapse of ureters. Postoperative plates show a good result which is also found clinically (Fig 3a-b).

These patients both had interposition operations. In the case where the trigone was prolapsed it was necessary to suspend the fundus very high beneath the urethra.

CASE 4 D.T., age sixty-nine. Complete uterine prolapse. Cystoscopy showed no great degree of prolapse of the ureters. In terposition operation. At operation there was a definite band from either side of the cervix at the level of the internal os, the two branches joining above in the middle line at the posterior portion of the trigone.

Postoperative result was good (Fig 4a-b).

CASE 5 J.L., age forty-seven. She was operated upon in Michigan fourteen years ago for "fallen womb," an abdominal operation. The condition recurred in two months and the doctor wanted her to have another operation. The note made on vaginal ex-

TONSILLECTOMY VS. ELECTRIC COAGULATION

The Present Status

JOSEPH D KELLY, M D , *New York City*

In reviewing the medical literature on the use of electricity and its application to medicine, I find that about every seven or ten years for the past half century, electricity in some form or other has been introduced as a cure-all, or as a substitute for surgery in some of its phases. The fad has run its course for a couple of years only to decline and reach its true status where it may remain for a while, until some enthusiast, or group of enthusiasts, revives it again for another period. However, we must acknowledge that with every wave of enthusiasm there is an improvement in the apparatus and in the method of application.

We, of the regular school, are quite often criticized for our obstinacy in refusing to accept all the wonders of electricity as applied to medicine. Because of the fact that there are some virtues in the newer methods, such as the different lights and high-frequency currents, the electrocoagulation and cutting current, there has opened up quite a field for the irregulars who have taken advantage of the opportunity and have advertised widely and enthusiastically in the second rate journals, the public press, and through syndicated articles. These advertisements have been so extensive, and the public has become so conversant with the application of electricity in some of its phases, that many of my confreres have been forced to equip their offices with electrical apparatus in self-defense, and to satisfy some of their patients who come to them demanding electric treatment. It is upon these regular men who have approached the problem with an open mind and who are willing to be converted, if the facts were sufficient to convert them, that I have depended for some of the data from which this paper is written.

I can recall that in 1924 or 1925 there was a considerable amount of written material on the subject of the use of radium for the removal of tonsils, and I

am sorry to say that some of the literature at that time had the sanction of, or was written by, some of the men who were prominent in otolaryngology. About this time, the writer, through the courtesy of one of the largest radium companies in America, had consigned to him a fair amount of radium to be used in the clinics of Manhattan Eye, Ear and Throat Hospital. Among the experiments we carried on at that time was the use of radium as a substitute for tonsillectomy. Our results were so disappointing that I took a trip to a distant city to interview the gentleman who had written so strongly about the virtues of radium as a substitute for tonsillectomy. He assured me that I must be away off in my technic or otherwise I would get results, and I left him feeling that my radium wasn't radium at all. However, a trip to the local special hospital and a talk with the interns and other doctors around the hospital convinced me that the gentleman in question was much too enthusiastic to give an honest opinion on the value of radium in removing tonsils. Hence, I have been very skeptical about much that I have read concerning the value of electrocoagulation.

Another method of removing tonsils which was being used about this time was x-ray, and many people were spending their money to have their tonsils removed by this method at twenty-five dollars per application. I am sure that many of you can remember the numerous and convincing articles which were written about the ease and thoroughness with which tonsils could be shrunk by x-ray therapy without sequelae, complications, or bad results. This phase, fad, cycle, or whatever you may call it, lasted about two years until the skin burns, dry throats, secondary tonsillitis, and necessary tonsillectomies became so numerous that the men advocating this form of treatment felt that it was the better part of discretion

lapsus uteri there are varying degrees of prolapse of the trigone of the bladder and the ureters and also varying degrees of descent of the urethra. This would seem to presuppose varying degrees of prolapse of the trigonum urogenitalis. Indeed, in some cases there is a little or no prolapse of the trigone and ureters and the portion of the bladder which is carried down is the posterior bladder wall or fundus. This is the portion which is closely bound to the anterior surface of the neck of the uterus and to the upper part of the wall of the vagina.⁶ This variation in the anatomy, we believe, may account for the fact that some cases are cured without any difficulty, and others return for operation time after time. Where there is prolapse of the trigone the repair seems much more often unsuccessful, and if the trigone is prolapsed it must be replaced to effect a cure. A simple repair will probably not suffice.

Prolapses also vary according to which wall of the vagina descends first and in some cases apparently the drag of a rectocele may pull the ureter down in a loop below the ureteral orifice.

Besides the position of the trigone and the ureters, in prolapsus, the position of the urethra is important, i.e., the degree of urethral descent or the extent to which the urethra is pulled away from the pubis. This is shown partly by the position of

the external meatus with relation to the pubis as seen in the x-rays. It is also shown by the direction which the urethra follows from the external meatus, i.e., whether its direction from the meatus is upward behind the pubis, or downward, as the patient lies on the table. This is easily shown by inserting a catheter into it and is not always obvious upon palpation. If the urethra is torn away from the pubis or if the trigone is prolapsed the case is difficult to cure and both must be replaced. In the interposition operation in these cases the uterus must be sutured near enough the pubis to prevent the recurrence of the cystocele, i.e., the suture through the vaginal tissues under the pubic arch and through the fundus should be high enough to sling the urethra and trigone up in their proper position.

Conclusion

In prolapsus uteri there may be associated varying degrees of prolapse of the trigone and the ureters. It appears that where there has been sufficient trauma to cause the trigone and ureters to prolapse, the case is more difficult to cure. Where the trigone and ureters and urethra have descended, they must be replaced to effect a cure. In difficult cases cystoscopy may be of help.

and granulation, a sloughing area. They say that in old people it is the procedure of choice. I do not see their argument here, for the writer and many of his conferees do not hesitate to operate on persons sixty-five or seventy years of age because they fear hemorrhages or complications. I do not believe that old people bleed any more than younger adults, and sometimes they bleed less, and they convalesce just as rapidly. I recently operated upon a doctor's father, seventy years of age, removing his tonsils under local anesthetic for a persistent iridocyclitis. In addition, this second class of men say that in luetic cases, electrocoagulation should be used. Who wants to take the tonsils out of a fellow in secondary lues, what is the need for it? If the patient is under treatment or has had treatment, he will not run any more risk than any other. If he hasn't had treatment, his tonsils should not be removed by any method until he has had sufficient treatment. As for tuberculosis, certainly you would not advise an operation upon an active case of tuberculosis, such as a bed case or a semi-bed case. When they are up and around, such cases even though they may occasionally have a positive sputum, do excellently under a local tonsillectomy.

The third type of man is the one who would have you believe that no other procedure should be considered except electrocoagulation and I think he is better depicted by quoting some of the statements he makes about the horrors of surgical tonsillectomies. The following paragraphs are taken from an extract of an article written by Dr. John J. Sullivan, Jr., of Scranton, Penn. (*Pennsylvania Medical Journal*, July 1933) in which he quotes from an article written by John Henry Millstone, M.D. of Chicago, and apparently Dr. Millstone writes the following paragraphs about the shortcomings of surgical tonsillectomies:

Electrocoagulation of the Tonsils

John J. Sullivan, Jr.

1 Complications The various complications encountered in surgical removal of the tonsils are practically nil in coagulation such as primary hemorrhages, aspirating pneumonia from general anesthetics, lobar

and bronchopneumonia, lung abscess, gangrene of the lung, and sudden toxemia and pyemia, due to a sudden absorption of mycotic emboli from suddenly opening wide vessels and lymphatic spaces in the tonsillar bed.

2 Economic advantages The removal of the tonsils by coagulation is an office procedure, involving literally no shock, whether it is done by multiple or one-stage method. It removes the expense and fear of being confined to a hospital. As the patient is ambulant, there is no time lost from his vocation.

3 Loss of voice Singers and public speakers dread and fear removal of tonsils. There is always the apprehension of the possibility of injuring their voices and robbing them of their livelihood. If coagulation is carried out properly, there is no interference or mutilation of the throat.

4 Hemorrhage The operation itself is a bloodless procedure. There is never primary hemorrhage. Sometimes there may be a slight secondary hemorrhage at the time the residue is desquamating.

5 Pain It is interesting to listen to the stories of individuals who have had their tonsils removed by surgical enucleation. It sounds like the stories of barbarism and the torture of prehistoric days. It is true there is some discomfort and slight reaction from six to twelve hours following coagulation, but never the agonizing suffering that is associated with surgical removal. In surgical removal the so-called capsule is removed, laying bare the muscles of deglutition. On account of the mechanical trauma of the snare, Sluder, dissector, scissors, and tenaculæ, every swallow of the patient is associated with terrific and excruciating pain.

6 Loss of sleep All of us are familiar with the long, restless, irritable nights of those patients who have had their tonsils removed by surgery, differing from the comfort exhibited by patients following coagulation.

7 Nourishment It is often from two to four weeks before a patient is able to partake of food following surgical removal. The loss of weight and cachexia are sometimes severe. Following coagulation, patients may immediately partake of soft diet and within three days return to their normal, regular meals.

The man who wrote this is the type of man who is selling the public, throwing electrocoagulation into disrepute, and killing whatever virtue it may have in

for them to fold up their tents and pass out quietly. So it has been many moons since you or I read an article advocating the use of x-ray or radium for the removal of tonsils.

Now in this period of depression, those who have positions and who have need to have their tonsils removed, but who cannot stay away from the office long enough to have them taken out in the orthodox manner, are told rather definitely by a well-meaning friend that it is not necessary for them to lose any time from their work to have their tonsils removed. All that is necessary for such a person is to find a general practitioner or some specialist who has been visited by a salesman from one of the many electric companies putting out high-frequency machines, this doctor will take out his tonsils in from one to fifteen visits to his office, and hence, it will not be necessary for the patient to stay away from work, and the fee will be commensurate with his means. He may run the risk of having a severe hemorrhage on anywhere from the fifth to the fifteenth day, he may have an acute attack of tonsillitis superimposed upon his already sore throat, and to help things along, a peritonsillar abscess may visit him about the third or fourth day following his first treatment, but the sad part of it is that, with these few complications, he still will not have his tonsils thoroughly removed.

I believe that many of us will agree that much of the present day enthusiasm for the electrocoagulation of tonsils has been brought about by the high pressure salesmanship of the companies selling high-frequency machines. They have invaded the highways and byways and have sold machines to men who have never before had a piece of electrical apparatus in their office. With their singing of "so much per visit" and "the price of the machine within the limits of all of us," they have foisted upon the public a great number of poorly trained electrotherapists.

Now in summing up the literature on this subject, we find that the men using electrocoagulation may be divided into three classes: first, those who have used electrotherapy for a number of years in some form or other and who have become well-qualified and expert in the use of

their apparatus, and who do not hesitate to say that anyone unfamiliar or untrained in surgical tonsillectomy should never attempt electrocoagulation of tonsils. Many of these men make the statement that it requires much skill and training to become expert with a high-frequency current. They also say that it is almost impossible to remove all of the tonsil tissue, that there are bound to be some fragments left at the upper pole and behind the anterior pillars, and that you must be very careful not to leave particles of tonsils buried under layers of epithelial tissue. They acknowledge, too, that you do get infection in the remaining stumps, that pharyngeal abscesses, tonsillitis during the process of electrocoagulation, destruction of pillars, edema of the uvula and pillars, cellulitis of the neck, edema of the larynx, post-operative hemorrhage, and severe post-operative hemorrhage, even resulting in death, may occur. The writer knows of one case of such a severe hemorrhage.

The second class of men, it seems to me, may be described as those younger and enthusiastic and fairly well-trained men who have taken up electrocoagulation very earnestly and are trying to make it fill a place for the cases which they deem unsuited for surgical tonsillectomy. These men tell us that it is not the operation of choice, that if there is no contraindication to surgical tonsillectomy, surgical tonsillectomy should be the procedure. However, they say that electrocoagulation, because of the absence of possibility of severe secondary hemorrhage is the operation of choice for cases of hemophilia requiring a tonsillectomy. I have never seen or heard of a hemophiliac who has had his tonsils removed by electrocoagulation, but I feel that the possibility of secondary hemorrhage in a hemophiliac is just as great from electrocoagulation as it would be from surgical tonsillectomy. Personally, I would much prefer to handle a case of secondary hemorrhage in a hemophiliac who had had his tonsils removed in the orthodox manner than one who had electrocoagulation. Those of us who have found it necessary to stop hemorrhages a week following surgical tonsillectomy know what a difficult thing it is sometimes, when you have an indurated, granulating surface. In electrocoagulation, you have, in addition to the induration

-than go for the remaining treatments. All to whom I have spoken have had pain and bleeding and one of my own patients, whom I sent to a confrere of mine for electrocoagulation, was in the hospital twice with hemorrhage and he got so disgusted with me for referring him and letting him in for coagulation that I have not seen him or his family since.

In a state the size of New York, where there are good surgeons of all types available, electrocoagulation as such for the removal of tonsils should play a very small part, and it should be used in the procedure for which it is best suited—that is, as a general cautery for the removal of lymphoid tissue at the base of the tongue, on the pharynx, on the nasal pharynx, or at the base of the tonsil, and for the shrinking of turbinates, and so

forth. If this were a community where careful surgeons were not available and where some of the things happen which they tell us *do* happen after a tonsillectomy in the smaller communities, there is no denying the fact that the patient might be better off with an incomplete electrocoagulation performed.

I do not want to be intolerant of any form of treatment or procedure which will supplant any of the older and more tried methods or which will offer a means of relief to anyone under my care, but I truly say that I cannot recommend electrocoagulation as the method of choice except in the most extreme and unusual circumstances, and then only when the patient has a full knowledge of what he is getting and what he may expect.

THE DOCTOR'S REPLY

To the frequent query, "Doctor, can you cure me?" suffering, hoping, trusting humanity through the ages has received many answers.

Dr Charlatan replies "Why, certainly! I have had unusual experience in treating your type of case and great success if I do say so myself. If you are not better in six months you can have your money back."

Dr Cocksure "Why, Madame, this is the type of case I specialize in. I have probably seen a dozen cases like yours in the last month. Just leave it to me and I can assure you that you will shortly be a well woman."

Dr Play-for-time "My dear lady, a case like yours is a very difficult one. Results cannot be obtained in a short while. I should say it will require two years to effect a cure of your disease. If you will come to my office regularly once a week over this period I can safely say you will then be a well woman."

Dr Pseudo-Honest "Madam, I never make promises of a cure. Only the charlatan does that. No real scientists, no true disciple of Aesculapius dare make such a claim, but this much I can say if you will follow my directions and treatment implicitly I can arrest your trouble. It will not be cured but it will not grow worse. Yes, I shall expect you to call at my of-

fice every month over an indefinite period of time. Remember I make no promises, only we shall arrest your trouble where it is."

Dr Foolishly Honest "Why, Mrs Doe, I have seen very few patients suffering from your complaint. It is true I have read about it and studied it a bit but I have not seen enough cases like yours yet to be very sure what to say to you. I shall be very glad to try a prescription on you I recently found in a Western medical journal, but you must remember it is all an experiment."

Dr Cruelly Honest "Madam, I promise nothing. I do not believe any doctor has ever cured a case like yours. I certainly have not. I advise that you do not waste any more money coming to me or to anyone else."

Dr Sensibly Honest "Mrs Doe, you have asked a very natural question and one that is difficult to answer. Of course you understand that doctors never make promises. All they can do is their best. I should suggest that you follow the advice I have handed you in written form. Let me see you occasionally, and if after a reasonable time, you are not better we shall frankly recanvass the situated ourselves, or call in someone else to help us."

—*Virginia Medical Monthly*

the eyes of the conservative, conscientious laryngologist

Having outlined these different types of men to you, I feel that you should know that there is considerable difference of opinion among the men in the different classes, particularly in the first and second, as to the methods to be used in electrocoagulation. Some will use desiccation alone, others will use coagulation along with desiccation, others, coagulation alone. Some say remove all the tonsil tissue, some say it is not necessary to remove all the tonsil tissue, but to stop when your patient's symptoms disappear. Others believe that a diathermo-cryptotomy is all that is needed, coagulating deep into the crypts of the tonsil and hence killing the bacteria and forming a sort of autogenous vaccine from the bacteria present in the crypts at the time of the electrocoagulation. Some advise never to get into the crypts of the tonsil because this procedure is likely to cause tonsillitis or a peritonsillar abscess. So you see all is not harmony among the electrocoagulationists, even they cannot decide upon a method which is satisfactory to all. So how can the novice know which way to turn when starting on his road to glory among the electrocoagulationists? The one way he has of learning is the method of trial and error with a standard high-frequency machine.

Let us now compare the two procedures, taking first the surgical tonsillectomy in the ordinary case. To the well-trained and conscientious otolaryngologist, tonsillectomy is truly a surgical procedure. It may be a simple one in some cases and a very difficult one in other cases. The operation does not consist in the use of the Sluder, or any modification thereof, or of the La Force, or any of the new-fangled instruments which are sold to the occasional tonsillectomist, but it means a careful dissection and snare, and more often, just clean dissection without the use of the snare. It is a fallacy to believe that the properly trained and experienced otolaryngologist is always stopping hemorrhages and running into complications, and that he does not have a large percentage of very excellent surgical results. In the modern hospital, the up-to-date tonsillectomy is a fifteen to

thirty minute operation including the time necessary to effect an efficient painless anesthetic, a complete enucleation with a minimum of trauma, a wholesome respect for tissue, and an orderly surgical technic of hemostasis. From the patient's standpoint, he will generally leave the operating room free from pain, but as the anesthetic wears off, there will be some discomfort, pain, and restlessness which can be controlled, he usually sleeps the best part of the night with an opiate and awakens the next morning to be helped by a warm throat irrigation, aspirin, anesthesin, and in eighty per cent of the cases, has orange juice, cereal, and coffee. With the general run of cases, this procedure is the rule and after a few days of discomfort, he is finished. Of course, the question of postoperative hemorrhage in surgical tonsillectomy arises. I think I am safe in saying that about four per cent of our local tonsillectomies have postoperative bleeding which generally is easily controlled either by plugging the fossa, re-injecting the area with novocain, checking up on the bleeding point, and either trying or putting in a suture. Bleeding in local cases usually occurs within six to twelve hours. Bleeding in electrocoagulation takes place before the fifteenth day and then the induration and sloughing make it practically impossible to locate the bleeding point and any attempt to put in a suture is followed by more hemorrhage, making it almost impossible to control the hemorrhage except by pressure.

Contrast the description I have given above with the person who is having his tonsils removed by electrocoagulation. He must make from fifteen to twenty visits to the coagulator at weekly intervals and leave with a sore throat which lasts twenty-four to forty-eight hours with intermittent bleeding and possible pain in his ear. The mental effect on some of the thinking, intelligent people who have let themselves in for a course of this treatment is terrific. One of them told me that he would think about it from one week to the next, and before going to the doctor would stop at the drug store for a sedative of some sort. Another became so disgusted that he had his tonsils removed by surgery rather

can go for the remaining treatments. All whom I have spoken have had pain and bleeding and one of my own patients, whom I sent to a confrere of mine for electrocoagulation, was in the hospital twice with hemorrhage and he got so disgusted with me for referring him and letting him in for coagulation that I have not seen him or his family since.

In a state the size of New York, where there are good surgeons of all types available, electrocoagulation as such for the removal of tonsils should play a very small part, and it should be used in the procedure for which it is best suited—that is, as a general cautery for the removal of lymphoid tissue at the base of the tongue, on the pharynx, on the nasal pharynx, or at the base of the tonsil, and for the shrinking of turbinates, and so

CHRONIC DIFFUSE GLOMERULAR NEPHRITIS

Diagnosis, Symptoms, and Treatment

HERMAN O MOSENTHAL, M D, *New York City*

Attending Physician New York Post-Graduate Hospital, Visiting Physician, Fourth Division, Bellevue Hospital

Past and Present Methods of Treatment

Chronic nephritis has been regarded as a disease whose signs and symptoms depend upon the pathology of the kidney. The treatment of this condition has consequently been carried out with the dominant idea of sparing the kidney as epitomized in the German expression "Schonungstherapie." The method consisted principally in rest, a low protein (lacto-vegetarian) diet, and residence in a warm dry climate. These therapeutic measures accomplished little, but were the best available, they are still used widely today though the study and experience of the past twenty-five years has shown that there are other means of treatment which, although not curative, will yield a longer, more useful, and more enjoyable life than the earlier regime of inactivity and protein starvation. Permanent bed rest is satisfactory for a few months in acute nephritis, but carried on indefinitely for chronic nephritis will result in disuse atrophy of the muscular and glandular tissues, a low protein diet lessens the excretory demands upon the kidney but results, *first*, in tissue deterioration including the kidney itself, *second* in the early development of anemia, and *third*, in a susceptibility to infectious diseases, notably tuberculosis, residence in warm dry climates uproots the patient—children cannot attend school, men cannot follow their occupations, and women leave a struggling household behind them, furthermore, hotel or boarding house life at its best is associated with discomforts and inconveniences which favor colds and infections that can be much more readily avoided by suitable clothing and shelter

in a wintry climate with routine family fireside care

Clinical Conception

The usual concept of nephritis is that it is a disease classified and fully described according to the histological picture of the kidneys. This is the pathologist's point of view and has been accepted in its entirety by physicians in a rather haphazard fashion. However, today the doctor can make diagnoses that are deemed to the pathologist. Functional pathology, the disturbances of physiological processes, has come to assume equal importance to anatomical pathology. Diagnoses such as uremia, hypertension, acidosis, can be confidently made by the physician and only hesitatingly, if at all, by the pathologist. Reasoning along these lines, we have for a number of years been making a clinical diagnosis of Bright's disease under six headings or phases, in the belief that each one of these, to a certain extent at least, exists and progresses regardless of the others and that the most effective treatment can be achieved if they are accorded individual attention and an unbending formula for the handling of chronic nephritis is discarded. The six aspects of chronic nephritis which would be appraised monthly by month and according to which treatment should be regulated, are

- 1 Kidney lesion (albuminuria—acutely the nephritis)
- 2 Edema
- 3 Hypertension
- 4 Impairment of renal function
- 5 Anemia
- 6 Uremia

Read at the Lake Keuka Medical Society Meeting, July 17, 1936

Treatment of Nephritis

The absorption into the circulation of the toxins of the hemolytic streptococcus, usually growing in the tonsil, the pharynx or the respiratory tract, are believed to be responsible for this condition in the kidneys. This was originally postulated by Lohlein in 1907 and has been verified by many investigators since that time. The condition may begin as a fulminating acute diffuse glomerular nephritis or in a cryptic fashion, so that it is discovered by chance on routine or on life insurance examination. The process may go on to complete healing, remain latent or progress to become a fibrosed, secondary contracted kidney, at any time with a lighting up of the infection there may be an acute exacerbation of the nephritis.

The obvious treatment is to clean out the foci of infection. Such operations as tonsillectomy or sinus drainage, can be carried out without damage to the nephritis, there may be an increase in the albuminuria or the edema for a few days but these soon subside and the condition returns to its preoperative state, removal of infectious foci will not improve an existing nephritis, this should be clearly understood by both physician and patient, eradication of the streptococcal infections will obviously lessen the chances of acute exacerbations of the nephritis and will, according to Longcope and his collaborators, retard the progress of slowly advancing lesions.

A low protein diet, the lacto-vegetarian diet of the last generation, it is now realized will not aid the kidney but may even favor cellular degeneration not only in the renal cells but throughout the body. A high protein diet will not damage the kidney but will tend to preserve the integrity of the whole organism. Some of the peoples of India who are strict vegetarians are prone to suffer with nephritis. The minimal quantity of protein in the diet regarded as satisfactory according to Peters, is seventy-five grams plus the quantity of albumin lost in the urine, larger amounts have been advocated but are not necessary.

Exposure to cold and wet, contact with persons who are suffering with "colds" or fever, excessive fatigue, in fact any and all causes which predispose to infections and, consequently, acute exacerbations

of the nephritis should be avoided. Light woolen underwear, when the modern trend can be overcome, is one of the best prophylactic measures.

The presence of albuminuria in itself is no contraindication to attendance at school or college, engaging in gainful occupation or following other duties. The possible exceptions are, for the reasons given in the preceding paragraph, the indulgence in competitive sports, outdoor occupations, and physical effort resulting in marked fatigue. Alcohol should be avoided, not because it is harmful in itself, but because through numbing of the sensibilities, it often is responsible for undue exposure that is instrumental in lighting up infections.

Treatment of Edema

The edema of diffuse glomerular nephritis is of three varieties.

1 The toxins of the hemolytic streptococcus, in acute glomerular nephritis or in acute exacerbations of chronic diffuse glomerular nephritis, damage the capillaries and increase their permeability to the contained blood.

2 Cardiac insufficiency which, as is generally appreciated, may result from prolonged hypertension in chronic diffuse glomerular nephritis, will bring about a type of edema similar to that produced by the failing heart under any circumstances.

3 A lowering of the blood proteins especially the albumin, is accompanied by a diminished osmotic tension in the blood and an escape of fluid into the tissues from the circulation. This is a characteristic symptom in the so-called nephroses, it may also occur in the course of chronic diffuse glomerular nephritis when it is regarded as a nephrotic component of the nephritis.

The treatment of this last form of edema only, is discussed here. It is obvious that the edema of acute nephritis and of cardiac insufficiency in many respects call for a different form of therapy.

Nephrotic edema, as first shown by Albert Epstein, is due to a lessening of the albumin content of the blood. This, because of the consequent lowered osmotic tension, allows the fluid to flow in excess through the vascular walls and accumulate in the tissues causing edema. According to Van Slyke and his associates, the critical level of blood changes which results in the edema is a specific

gravity of 1.023, a total protein content of five per cent, and an albumin concentration of three per cent. One of the main reasons for the loss of blood protein is the albuminuria, whether or not this is the sole explanation of this whole disturbance, remains to be determined. Page has shown that denervation of the kidney will check proteinuria without interfering with the function of the kidney. Whether or not this surgical procedure is feasible in these cases is a matter for future experimentation and study.

The most obvious remedy is the administration of a high protein diet. This certainly does no harm, it appears to check or ease the condition in many cases, though the general experience does not bear out Epstein's contention that it is a cure in most instances. The amounts of protein advocated for daily consumption range from seventy-five to well above 200 grams. The formula of Peters that seventy-five grams plus the amount lost in the urine, is a good one.

Salt restriction is as valuable today as it was when first reported by Widal and Javal, and by Strauss. It has been established that the sodium and not the chloride part of NaCl favors the production of edema. This makes it clear why potassium chloride, about three grams a day, can be advantageously substituted for the sodium chloride, it also shows why most of the "salt substitutes" are not worth considering because they are a combination of sodium with other acids (for instance sodium malate) and since they contain sodium have no advantage over sodium chloride.

Thyroid administration has been widely advocated. It was first suggested because in nephrotic edema the basal metabolism is low. It is an open question whether the basal metabolism is actually lowered or only seemingly so. According to the height and weight standards, it is less than normal, but it is obvious that the edema—that is, fluid accumulation which does not consume oxygen—may give the basal metabolism false values. From the practical point of view, these patients tolerate thyroid medication in large amounts while their plasma cholesterol is high, when it approaches normal the remedy should be discontinued. In one

case of nephrosis as much as ten grams of the thyroid extract per pound of patient were used daily and only produced symptoms of hyperthyroidism when there was a drop in the plasma cholesterol. The effect of thyroid on the edema is not always satisfactory though the same may be said of other forms of treatment.

Diuretics must be managed with great care. Water and sodium chloride, the blandest and also among the most efficacious diuretics, are already present in excess in the tissues of the patient and consequently their administration must be restricted and not increased. Urea in ten gram doses three times a day, is valuable. It should be given in cold water, flavored with fruit juices, after meals, it may be administered with impunity unless the blood urea is at a high level—forty mg. or more of urea nitrogen per 100 c.c. of blood. High protein feeding results in an increase of blood urea which doubtlessly has a diuretic influence.

Salts which bring about an acidosis, especially ammonium chloride and ammonium nitrate, have been advocated as diuretics for use alone or in conjunction with other drugs especially salyrgan and mercupurin. These salts as a rule do not accomplish more than salyrgan or mercupurin alone and their use may be dispensed with, except when diuresis cannot be produced without their aid.

The manner in which digitalis affects the urinary flow has always been a controversial matter. Whenever there is the least sign of cardiac dilatation, whether there appears to be cardiac failure or not, it is worth while to resort to digitalis. It often produces diuresis, whether it does so by relieving renal congestion or by direct action on the kidney, or both, is an open question. The purine products and mercurials are more effective when combined with digitalis. Digitalis is worth a trial in most cases.

The purine derivatives have enjoyed a wider use as diuretics than most of the others. They have not proved effective except when cardiac failure exists. They should be used intermittently, every third or fourth day, like most of the diuretics. Their action is enhanced by digitalis, rest, and other measures which stimulate the circulation. Caffeine or one of the caf-

eine salts in three to ten grain doses, Theobromine (theobromine sodium salicylate or "diuretin," 5 to 10 grains, three or four times a day), Theophylline or "Theocin," three to five grains three times a day, are the ones most commonly used. Theophylline is the most effective, it is prone to cause nausea and vomiting and, as mentioned above, should be used every third or fourth day.

Mercury has long been recognized as an efficient diuretic but it is well-known that calomel and bichloride of mercury may damage the kidney severely even in small doses. A mercurial compound for intravenous use, "novarsuroil," was introduced a few years ago, this proved to be treacherous since it often entailed severe reactions. Since then "salyrgan" and, more recently, "mercupurin," have been put on the market. Why the mercury in these preparations is not as harmful as in others is not clear, but clinical observations bear witness to the fact that they are not. I have one patient suffering with permanent cardiac insufficiency, who during the past four years, has received fully 300 injections of these drugs without any sign of mercurialism or harm to the kidneys. Salyrgan or mercupurin are given in two c.c. doses intravenously or intramuscularly, not more frequently than twice a week. There is a distinct hazard of necrosis with subcutaneous injection so that the intravenous therapy should be carried out under expert guidance only. The mercupurin is the better diuretic as a rule and is less irritating to the subcutaneous tissues. The question of the advisability of using these drugs in the presence of chronic diffuse glomerular nephritis constantly arises. Until there is a greater experience with these mercurials they should not be resorted to under these conditions unless there is the necessity for saving life from the uncontrolled accumulation of fluid, as sometimes occurs beneath the skin and in the body cavities. In some of these cases these mercurials have proved to be good diuretics and apparently have not injured the kidney.

There are some curious facts about these mercurial diuretics. Mercupurin contains theophylline, because of this it is presumed that its effect upon the kidneys

is enhanced and the irritation of the subcutaneous tissues is diminished. Recently the mercupurin without the theophylline has been put upon the market as a suppository called "mercurin." Christian in America, and Parkinson and Thomson in England have reported favorable results with these suppositories. I have used them and found them to augment the flow of urine though less than the intravenous or intramuscular injections. The reason for omitting the theophylline in the suppositories is that they do not produce diuresis when they contain this material. This is an unexplained fact that for the present we are accepting on the statement of the pharmaceutical house which is responsible for the mercurin and mercupurin. By the same source, I have been informed that mercupurin when given by mouth has no effect on the urinary elimination.

The accumulation of fluid may be so great as to require tapping of the chest or abdomen for relief of the mechanical pressure on the lungs, the heart, and the circulation. Under these circumstances, thoracentesis or paracentesis should be done. The drawback of such removal of fluid is that a certain and considerable amount of protein is taken away at the same time and protein loss in this disease is something we wish to avoid if possible, and also the tapping operation in chronic nephritis, especially of the abdomen, is often followed by infection.

Treatment of Hypertension

Hypertension is a common accompaniment of chronic diffuse glomerular nephritis. It may exist either in the absence or in the presence of renal insufficiency. The arterial tension in this disease is prone to acute exacerbations which occur for no apparent reason and which may be the cause of death.

The elevated blood pressure produces the same secondary effects as in essential hypertension, that is, the heart is most likely to be affected with coronary disease and cardiac failure and next in frequency, cerebral arteriosclerosis with its palsies and "hypertensive encephalopathy" becomes a factor in the situation.

The detailed treatment of hypertension will have to be omitted here since it

would occupy more time than we are entitled to give it in this paper. There are only a few points in regard to it that might be stressed. Intermittent, but not complete, rest and mental relaxation accomplish more for this disorder than any other form of treatment, the hypertensive patient should be examined frequently to gain his confidence and to meet his needs, especially incipient cardiac failure, which usually responds very well to treatment, diet should be directed toward relief from overweight, that is, low carbohydrates and fats in the obese, and proteins whether as red meat or white, eggs or fish, may be given with impunity, they do not elevate the blood pressure. Frequent small venesections when the red cell count is above five million, are of distinct value.

Treatment of Impaired Renal Function

Symptoms due to renal insufficiency do not appear until the urea nitrogen in the blood rises to a level of at least sixty mg per hundred c c. Consequently, the proteins in the diet need not be curtailed until that figure is reached. The restriction of proteins will favor the development of an inevitable anemia and malnutrition, and should, as previously discussed, be delayed as long as possible.

The early stages of renal insufficiency are signaled by an inability to concentrate the urine as shown by a lowering and fixation of the specific gravity. When this occurs there is an increased output of urine especially at night—the well-known nocturnal polyuria. The rise in urine volume will for a long time serve to maintain an adequate elimination of urinary solids. The main point in the situation is that under no circumstances should the fluid intake be curtailed but rather that the patient should be encouraged to satisfy his thirst so as to maintain the "compensatory polyuria."

Sometimes excessive thirst and polyuria are relieved if the salt in the diet is drastically restricted. Edema is a complicating factor early in the course of a chronic diffuse glomerular nephritis and usually, before renal insufficiency and compensatory polyuria become a part of the clinical picture, so that as a rule it

is not necessary to consider renal insufficiency and edema at the same time.

Treatment of Malnutrition and Anemia

Malnutrition and anemia so severe as to constitute a cachexia, occur in every case of chronic nephritis when a considerable amount of the kidney tissue has been destroyed. Animal experimentation shows that this comes about when three-quarters of the renal parenchyma more or less is removed. The fact that this does take place is not disputed, but the reason for it is not clear. From the therapeutic point of view, it is wise to anticipate the occurrence of the anemia and for this reason to insist on a rather high protein diet, thus preventing the development of the anemia as far as possible. The patient should be examined frequently, and when the hemoglobin and red cells begin to fall off, liver and iron medication will help the situation somewhat though they will not do away with it completely. Arsenic because of its possible toxic effect on the kidney, has not been tried extensively. When the anemia becomes marked and a regeneration of the hemoglobin and red cells cannot be brought about by the usual means, it is in order to consider blood transfusions.

Transfusions of blood may be given to cases of chronic nephritis with perfect impunity if the preoperative matching of blood is carefully carried out. Blood transfusions will not produce uremic symptoms, will not increase the blood pressure, will not damage the kidney, and will not result in reactions any more frequently than in persons not affected by the nephritis. The transfusions of blood will remedy the anemia and thus improve nutrition and restore physical vigor, beyond this, nothing should be expected from the transfusions. They will not improve renal function, diminish symptoms such as headache, or relieve the edema.

Transfusions of blood should be used before terminal renal insufficiency makes its appearance, so that the patient will receive the full benefit from them. When they are carried out early in the course of the nephritis their effect will be a lasting one and the red blood cell count be maintained at a more or less normal level.

or a long time. When they are carried at late in the disease, usually the anemia rapidly progressive in spite of the transfusions.

In the cases of nephritis associated with anemia, it usually requires a considerable amount of blood to combat the anemia. 500 to 1000 c.c. of blood may be given at one transfusion. The first, and sometimes even the second transfusion may fail to evoke any response as far as the red blood cell count is concerned. Why this is so, is not clear. The second or third transfusion as a rule brings about a rise in the red cell count and it may require even a fourth before the red cell count and hemoglobin are restored to an approximately normal level.

With the former treatment of nephritis which called for a lacto-vegetarian diet from the beginning, anemia and malnutrition proceeded much more rapidly and would frequently outstrip the development of impairment of kidney function and retention uremia. These patients often died as a result of the under-feeding before the uremia would overtake them. When these cases are encountered, their life may be very much prolonged by the judicious use of blood transfusions. In any event at the present time one of the causes of death in chronic nephritis, namely that from malnutrition and anemia, can be set aside by the transfusion of blood.

Treatment of Uremia

The term "uremia" as applied to chronic diffuse glomerular nephritis really implies three different conditions: *first*, the manifestations due to the effect of streptococcus toxins on the central nervous system which accompany acute exacerbations of a chronic nephritis, *second*, the manifestations of hypersensitive encephalopathy, *third*, the effect of renal insufficiency, that is, the retention of urinary excretory products within the body. It is often very difficult to separate these three forms of irritation of the central nervous system for they may occur in combination. It is only the uremia of renal insufficiency often spoken of as retention uremia or asthenic uremia (for the fact that convulsions are not an outstanding symptom) which will be taken up here.

Retention uremia is usually the result of a lowering of the urinary volume, that is, the compensatory polyuria which has enabled the patient to carry on in spite of the diminished amount of kidney tissue. As a routine procedure, it is indicated to administer large amounts of fluid so that the kidneys will have ample material from which to form urine. The skin should not be allowed to become dry. Three to four liters of fluid a day should be given. When there is vomiting, this should be administered as ten per cent glucose in normal saline solution.

The symptoms such as headache, nausea, and vomiting are best controlled by fairly large doses of chloral, in most cases this can be given advantageously by rectum, thirty to sixty grains of chloral at a time in a small amount of starch paste is absorbed readily and is usually effective, when given by mouth it may be administered in smaller doses—ten to twenty grains repeated at intervals if needed. Chloral apparently does not depress the circulation and does not cause any lasting depression or "fogginess" as the barbiturates or morphine products are prone to do. It has an extremely disagreeable taste which nobody thus far has succeeded in disguising, so that the rectal route of administration is often advisable.

When possible, the blood determinations of calcium and sodium chloride at frequent intervals are of help and furnish guides as to when to give and withhold salt and when to administer calcium by mouth or vein. When these blood determinations are not available it is advisable to use calcium liberally and be sure the patient is receiving at least some sodium chloride. The twitchings so characteristic of retention uremia are supposed to be due to a deficiency of calcium in the circulation, however, they are not necessarily relieved by the calcium medication.

The diet for these cases should always be one as low as possible in protein, and high in fat and carbohydrate content. In this connection it is worth while remembering that sugar, corn starch, and tapioca are three foods made up of carbohydrates without any admixture of protein and they, together with fruits and fruit juices, constitute the ideal diet for retention uremia. Alcohol is digested like the car-

bohydrates and may well be used especially in the shape of sherry or port for nutrition and for relief of the monotony of a proteim-free diet

Summary

The treatment of chronic nephritis today recognizes the fact that this disease of the kidneys is made up of several elements which demand individual attention. These are the lesion of the kidney itself, that is, the nephritis, edema, hypertension, impairment of renal function, malnutrition and anemia, uremia. These phases of nephritis are not only treated when they arrive, but the administration of drugs and diet should attempt to anticipate their appearance. All treatment, especially dietetic therapy, is aimed to

maintain the patient in good physical condition and to make no attempt to deny the body necessary nutrition because of efforts at shielding the kidney which are now recognized as being of no value, stress is put upon the idea of feeding a sufficient quantity of foods with a high protein content, especially meats, which do not injure the kidney, alleviate edema, do not cause a rise in blood pressure, prevent malnutrition and anemia, and need only be curtailed when a considerable degree of impairment of renal function makes its appearance. In other words, a high protein diet can be used for the treatment of every phase of chronic diffuse glomerular nephritis except when retention uremia is threatening.

PERSUASIVE APPROACH WITH THE INFECTIOUS SYPHILIS CARRIER

According to Louise Brown Ingraham, Philadelphia (*Journal A M A*, Dec 12, 1936), the sterilization of the infectious syphilis carrier is a problem that proceeds from the known syphilitic person to the identification, examination and treatment of the unknown.

Compulsion and persuasion are two mediums of accomplishment. These may be applied separately or integrated. Intrusion on the privacy of the patient and the use of his confidential disclosures are important considerations in carrying out the volitional or persuasive approach. The voluntary approach implies freedom of initiative on the part of the follow-up personnel in developing a personalization of appeal. It involves experimentation in technics of persuasion. The confidence of the patient and his voluntary response are entirely dependent on the development and application of these skills.

The voluntary approach as interpreted in this study is not a feeble touch and go process. Rather is it a tender but direct cultivation of the interest of the patient sometimes through friendliness, sometimes through sympathy, often by a generous performance of some personal service. There must be a quick intuitiveness to grasp opportunities, to sense resistance or change in attitude, with a readiness to advance, to retreat, to withdraw. The attention to the patient's interests cannot be transitory, a caring today, tomorrow forgetting. It must result in a constant watchful stimulation

during the entire interval required for case finding. The subject must be kept alive or the patient will forget and cease to bother.

The initial interview is the foundation of all hopes for success with the syphilitic individual. The intelligent interpretation of syphilis may even mean the beginning of effective person to person propaganda for the control of this disease. Effort should be constantly directed toward teaching the patient the manner in which he may seek out his own contacts and persuade them to report for medical examination. The question of whom is to take the initiative in getting the contact in for examination is decided by agreement between the social worker and the patient after the name of the contact has been secured.

The ultimate finding of the whereabouts of the contact is the outcome of the usual methods of searching a neighborhood. To conceal with diplomacy the name of the former is essential and it lessens the possibility of mistaken identity. To draw on his sympathy by suggesting the guilt and humiliation he would feel if he were held responsible for infecting some one is to stir his imagination and save the day. Reluctance to be identified implies the apologetic attitude of the unknown partner, while establishing the knowledge of a sense of responsibility on his part. It changes the emphasis from accusation to communication. The contact senses protection, and confidence matures.

BISMUTH BY MOUTH IN THE TREATMENT OF SYPHILIS

Preliminary Experimental Study with Bismuth Chloride (Bismutrate) in Rabbit Syphilis

CHARLES ROBERT REIN, M D and MARION B SULZBERGER, M D, *New York City*
From the Skin and Cancer Unit of the New York Post-Graduate Medical School and Hospital,
Columbia University, Dr George M MacKee, Director, Service of Dr Fred Wise

Following the successful introduction of bismuth in the treatment of syphilis by Sazerac and Levaditi,¹ many attempts were made to administer the drug by the various possible routes. The results of these attempts may be summarized as follows

1 The intramuscular method has proved of practical and general usefulness because the bismuth which is readily absorbed from the intramuscular depots is relatively non-toxic.

2 The intravenous method, however, has fallen into disrepute because of the high toxicity of bismuth by this route

3 The inunction method has also been discarded owing to the inadequate absorption of the drug from the skin.

4 The oral method has been abandoned since the early investigations of Levaditi,² and those of Fournier and Guenot,³ demonstrated its complete inefficacy

However, there have been numerous reports in the literature of severe bismuth intoxication following the oral administration of bismuth salts when administered for example, as a contrast medium in x-ray diagnosis and in the treatment of gastrointestinal disorders. These reports suggest that an occasional extensive absorption of bismuth has taken place from the gastrointestinal tract

Serefis⁴ studied this phenomenon and found that nearly all bismuth salts are converted into bismuth chloride by hydrochloric acid, and that this bismuth chloride formation also takes place in the presence of any other acid, or in the presence of chlorides if lactic acid or lactates are likewise present. Serefis believes that if there is an inflammatory injury of the stomach wall, the acid solution of the bismuth chloride may there be ab-

sorbed. Under normal conditions, however, the bismuth chloride is precipitated as the insoluble bismuth oxychloride in its passage into the alkaline intestinal fluid, and is not absorbed. Under certain conditions, however, the bismuth chloride may combine with polyvalent alcohols and organic acids, or salts of organic acids, in the stomach itself, thus forming complex bismuth compounds. These complex bismuth salts are not immediately precipitated in an alkaline medium and can therefore be absorbed from the intestine

Accordingly, Serefis attempted to evolve a preparation of bismuth chloride which would reach the intestine in an absorbable state. From *in vitro* experiments, he concluded that a stable bismuth compound could be formed by the addition of a polyvalent alcohol (glycerin) and an organic acid (sodium citrate) to the bismuth chloride. To this he added liver extract, because Levaditi and Nicolaï⁵ had long previously demonstrated that organoextracts greatly increase the spirocheticidal power of complex bismuth compounds. This complex bismuth solution, when neutralized with sodium hydroxide, could be ingested in large amounts without producing any irritation of the gastric mucosa. In addition it was not precipitated in an acid, neutral or alkaline medium, nor by dilution

Mulzer and Serefis⁶ report that they have employed such a preparation of stabilized and absorbable bismuth chloride in both rabbit and human syphilis with favorable therapeutic results. They also found that a considerable amount of bismuth was continually excreted in the urine of those individuals who received

this preparation by mouth, thus furnishing additional proof that the bismuth was actually being absorbed from the gastrointestinal tract

These studies, in addition to the recent investigations of Kolmer,⁷ led us⁸ to re-investigate the efficacy of the oral administration of bismuth in experimental syphilis. It seems that oral administration of bismuth in the treatment of syphilis fell into disrepute for two definite reasons. *First*, because there has been no preparation of bismuth which could be adequately and consistently absorbed from the gastrointestinal tract, *second*, the oral administration of bismuth or any other

antisyphilitic remedy all too frequently leads to under-treatment. Even though patients are told specifically that this type of medication will not suffice, they are apt to depend on oral medication, especially when they are clinically free of symptoms

For this last reason we do not feel that it is advisable to administer antisyphilitic remedies by mouth as a routine procedure in all stages of syphilis, this is especially true because the use of intravenous and intramuscular injections of the modern drugs is not only increasingly effective, but can, today, be carried out with relative ease in the majority of cases. More-

over, it is sociologically contraindicated to advise oral medication in patients with early syphilis, because by this method the resolution of the lesions is, generally, much slower and the control of the infectiousness of the disease would be inadequate. There are, however, definite indications for oral therapy. Kolmer,⁷ in his recent article, clearly outlines the following indications for the oral administration of bismuth, with which we are in general agreement:

1 In the treatment of acquired or congenital syphilis between courses of arsphenamine or bismuth injections. This affords excellent means of continuing treatment during the intermissions between the courses of injections, or when the patient is unable to receive injections for a long period of time.

2 In the treatment of syphilis of long standing, especially where cardiovascular syphilis exists. This would tend to prepare the patient for other forms of medication and thus prevent Herxheimer reactions.

3 To be given in conjunction with injections of arsphenamine or neoarsphenamine in a so-called "combination" type of treatment.

4 To be given to those syphilitic patients who find it impossible to have medication by intunction or injection, either because of intolerance, or on account of some other reason.

It seems to us that in addition to these indications of Kolmer's, the oral administration of an absorbable bismuth may be of definite value in the "prophylaxis" of syphilis and thus was one of the points borne in mind in our present experiments.

The bismuth chloride preparation employed in our experiments was supplied in large tablets of light brownish color, each weighing five grams, and containing 200 mgs of metallic bismuth. These tablets were not easily soluble in water, but when crushed were brought into a uni-

form chalky aqueous suspension of agreeable taste, resembling that of licorice. This preparation (Bismutrate[†]) is said to contain the following constituents:

Complex Amino-Acid Bismuth salt of oxytricarballic acid (bismuth chloride combined with glycerin, sodium citrate and liver extract.)	67 14%
Sacch. alb	25 60%
Talcum	3 30%
Stearic acid	0 65%
Oleum anisi	0 01%
Succ. glycyrrh	3 30%

Employing this preparation, we carried out the following experiments.⁸ Fifteen adult male, grey chinchilla rabbits, weighing approximately 2500 grams each, were used. These were inoculated on March 21, 1935 with an established and proved virulent strain of *Treponema pallidum*. The inoculations were performed bilaterally, both in the scrotum and testes.

For the purposes of experiment, the animals were divided into four groups as follows:

Group I *Prophylaxis** Rabbits 64 and 67 received Bismutrate on each of three successive days immediately prior to inoculation.

Group II *Prophylaxis plus primary abortion** Rabbits 62, 65, and 66 each received Bismutrate on three successive days immediately prior to inoculation and on four days immediately after inoculation.

Group III *Secondary abortion* Rabbits 51, 52, and 53 received Bismutrate beginning 42 days after inoculation (12 days after the appearance of the primary lesion.) Treatments were given approximately three times weekly during a period of thirty-nine days (a total of 17 treatments per animal).

Group IV *Positive controls* Rabbits 50, 58, and 68 were inoculated but received no treatment.

[†] We are indebted to the Neo-Products Company for placing a large supply of this preparation at our disposal.

* In speaking of the prevention of venereal diseases, "prophylaxis" is the word usually employed to designate those procedures which are carried out *after* 'suspicious' contact, i.e. after infection may have taken place. Strictly speaking, it would seem that "prophylaxis" is not quite the correct term to apply to these procedures, for after infection has taken place, the disease is already present, although not manifested. We, therefore, in our present studies, distinguish between (1) *Prophylaxis* i.e., preventive measures employed *before* infection or before inoculation (2) *Primary abortion* i.e., measures employed during the primary incubation period, *after* infection or inoculation but *before* the appearance of any manifestation (3) *Secondary abortion* i.e. measures employed during the secondary incubation period after the appearance of the primary manifestations, but early enough to abort the course of the disease. (4) *Treatment* i.e. measures employed during any stage of the disease. In this classification, what is ordinarily called "prophylaxis" would be classed as *primary abortion*.

In this classification, what is ordinarily called "prophylaxis" would be classed as *primary abortion*.

Each treatment consisted of the administration of a suspension containing one five gram tablet of Bismutrate (200 mgs of metallic bismuth) in approximately ten c.c. of distilled water. The suspension was introduced into the stomach through a #12 Fr rubber catheter. This tube was passed through the oral cavity and esophagus into the stomach and the suspension injected by means of a syringe.

The sera were all examined at weekly intervals, beginning with the first examination on the day of inoculation. The Wassermann, Kahn, and Kline tests were performed on all specimens, but since the results were more or less analogous, the Kline test results only are plotted in our graphs (Charts I & II). Typical chancres appeared only in the animals of groups I, III, and IV. However, the animals of group II (i.e. those receiving a combination of both prophylaxis and primary abortion treatment) at no time developed chancres or any other clinical or serologic manifestations of syphilis (Chart II). In those animals in the other groups in which chancres developed, dark field examinations were performed with uniformly positive findings.

As stated, chancres developed in all the animals of group I (prophylaxis group), and in all of group III (secondary abortion group), and of group IV (positive control group). Furthermore, the serologic findings became positive in all three of these groups. However, group I, comprising the rabbits which received Bismutrate before inoculation only, presented a marked delay in the development of positive serology. This seems to indicate that sufficient bismuth was absorbed to delay the development of positive serology. Nevertheless, because of the small number of animals we should not like to attribute too much weight to this finding. However, as can be seen by Charts I and II, the results in Group II (animals receiving prophylaxis plus primary abortion treatment, consisting of three administrations of Bismutrate on the three days immediately before and on four days after inoculation) were in sharp contrast to those in the other three groups. These animals at no time developed chancres, positive serology or any other manifestations of syphilis.

The lymph glands of these animals (62, 65, and 66) were removed and transplanted into new animals (July 2, 1935). These new animals did not develop any clinical or serologic evidence of syphilis. In addition, animals 62, 65, and 66 were reinoculated with the original strain on July 17, and all three developed testicular chancres and positive serology. The results of these experiments are additional proof that syphilis infection did not occur in the animals of group II (prophylaxis plus primary abortion). As the same strain was used there can have been no question of monoinmunity. The "take" of the reinoculation demonstrated that this negative result at first infection was not attributable to a silent course ("Nuller"-Kolle).

In a recent study, Kemp and Rosahn¹ also employed Bismutrate in the treatment of early syphilis in the rabbit. They found that twenty-four daily doses (20 mg of metallic bismuth per kilogram) failed to alter materially the course of early syphilis in five of the six animals treated. Similar unsatisfactory results were obtained with twenty-four daily doses of fifty mg metallic bismuth per kilogram.

The factors in our experiments differed from those of Kemp and Rosahn as follows:

1 Kemp and Rosahn employed twenty four daily doses each containing twenty five or fifty mgs metallic bismuth per kilogram. We used 200 mgs of metallic bismuth per treatment (approximately 80 mg of metallic bismuth per kilogram—group III). Treatments were given approximately three times weekly during a period of thirty-nine days (a total of 17 treatments per animal).

2 Kemp and Rosahn gave the Bismutrate only after inoculation. In our groups I and II the Bismutrate was administered before as well as after inoculation.

Comment

This report is submitted with full knowledge both of the danger of drawing conclusions from such a small series, and of the fallacy of attempting to apply the results of animal experiments to human conditions.

Our findings, together with those of Kemp and Rosahn suggest

1 That this oral bismuth preparation requires further investigation both regarding absorption and regarding possible therapeutic effects

2 That this preparation may, when given in large doses, permit the absorption of bismuth from the gastrointestinal tract of rabbits

3 That there is some possibility of successful prophylaxis and primary abortion of rabbit syphilis with the preparation, and that this effect is worthy of further study

Discussion

DR. A. BENSON CANNON, *New York City*—While I have had no experience in the oral administration of bismuth in animals, I can readily appreciate the value of this work of Doctor Rein and its application to the treatment of syphilis in human beings. The results of his experiments are exceedingly interesting and well presented in this paper, and while the doctor has been most modest in his conclusions I am sure all of us know how much the working out of such problems adds to the sum total of knowledge of the effective treatment of syphilis.

About two years ago I became very much interested in the administration of bismuth by mouth, and Dr C N Myers and the pharmacist at the Vanderbilt Clinic were good enough to make up several gallons of metallic bismuth in glycerine. This we administered in maximum doses orally to a group of patients with primary and secondary syphilis. Later, I was supplied with a quantity of "Bismutrate" which I gave to another group of patients with primary and secondary syphilis. The observation of each case extended over three to four weeks and during that time there was no appreciable change in the character of the lesions except that in several patients they were decidedly worse and there were still numerous spirochete demonstrated in dark-field examination of secretion taken from the chancre and secondary lesions, especially in the condylomatous lesions. In each instance after the administration of one dose of old arsphenamine, there was begun a rapid disappearance of lesions. Several of the patients developed bismuth lines on the gums and a stomatitis and sometimes other toxic symptoms of absorption of the drug. Most of the patients objected to the

disagreeableness of taking Bismutrate and of its interference with their digestion.

These adverse observations caused us to abandon the treatment of syphilis with oral bismuth. I am sure, though, that we had no patients come to us until several weeks had elapsed after their exposure.

Dr Raiziss in a personal communication said that he had found that the injection method of administering bismuth was at least five times more effective than the oral.

The results that Dr Rein had in group II were particularly gratifying and should encourage further experimentation with this drug.

DR. HERMANN FEIT, *New York City*—I shall never forget my first experience with a French preparation (Trepol) which was brought from Paris before bismuth was available in Germany. We used it on a patient with late secondaries on the scrotum which was treated by Prof Erich Hoffman with all kinds of arsenicals and mercury preparations without any change. After a few trepol injections the lesions completely disappeared. When Dr Rein now introduces a bismuth preparation which probably can be used in men by mouth a gap will be filled because pain is still an impediment in intramuscular bismuth therapy. It would be interesting to determine the arsenic content of the new preparation as all bismuth preparations contain this metal as Abramowitz has shown and the possibility of which we all had suspected. I have shown a patient at the Academy of Medicine with an exfoliating dermatitis who had only bismuth therapy. The dermatitis naturally could not be distinguished from a salvarsan dermatitis.

MUNICIPAL SYPHILIS CONTROL

THOMAS F LAURIE, M D , *Syracuse*

Since January 1, 1936 the plan for control of syphilis as outlined by the New York State Dept of Health has been in operation in Syracuse. Although too early to draw reliable conclusions, it is worth-while to study the results so far obtained in an effort to make improvements.

The activities of the Bureau consist of the following:

- 1 Diagnosis and treatment.
- 2 Epidemiological investigations
- 3 Publicity and Health education
- 4 Instructions and information for physicians

We have a Central Dispensary for the general medical care of indigent patients. In this building is the clinic for Syphilis and Dermatology. Gonorrhea is treated in the Genito-Urinary and Gynecology Clinics in the same building. The clinic has adequate equipment and personnel for the diagnosis and treatment of syphilis. The staff is paid. No physician receives less than \$5.00 for each clinic period. The office of the epidemiologist and his assistants is in close proximity to the clinic. Housed in the same building is the Bureau of Laboratories of the Syracuse Department of Health, all dark-field and serological examinations are made there, and also the supply stations for drugs supplied by the State Health Department.

To prevent the spread of syphilis chief interest centers in the following:

- (1) Detecting the early cases,
 - (2) treatment at the earliest possible moment,
 - (3) searching for the contacts and immediate treatment of them if infected.
- The late cases are of little importance from the standpoint of syphilis transmission. Our main source of information is the Laboratory. All positive dark-field and serological examinations are reported to the Bureau of Social Hygiene office as

soon as possible. If a private patient has a positive dark-field his physician is called and asked to find out if possible the source of infection and to fill out the form prescribed by the State. The Bureau, if requested, will assist the physician. If a clinic patient, the same procedure is carried out by the Bureau. Positive serological reports are examined and an effort made to classify these patients as early or late infections. Private physicians are asked by letter whether the cases are early or late infections. Contact with hospitals is maintained through Social Service and in this way reports are obtained. The response from private physicians has been extremely gratifying as noted in the tabulations. Most of these reports concern late cases however. Reports of early cases are relatively few as are also the number of dark-fields as compared to the number of positive serological examinations in the past few years. Whether or not this is due to a decrease in the number of infections or neglect of physicians to use the laboratory, it is impossible to say at this time. We endeavor to promote by every possible means the importance and necessity of dark-field examination of all genital lesions. No real epidemic has been encountered. This is a good sign providing our efforts at epidemiological investigations have been dependable. It is our belief that finding contacts in large centers is more difficult than in the rural communities. This is probably due to several reasons including the following: (1) In cities people are more liable to move from one location to another, (2) More complex social order, (3) Prostitution more common. We have a negro population of 2,500. Efforts are being made to correct regrettable conditions of the colored people. All early cases and those considered potentially infectious, are registered in

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 29, 1936*

our files All information regarding each patient and contacts is kept in a separate folder So far we have twenty-four registered patients, of these six are very early cases and the rest are those under treatment at the Dispensary

A comparison between rural and urban epidemiology is interesting Dr Philip J Rafle, District State Health Officer, permitted me to use a report of an epidemic which occurred in and about a nearby village during 1934 and 35.

A young man, with early syphilis under the care of a private physician named a twenty-year old girl, as the source of infection He denied other sex contacts This girl was promptly placed under observation, and found to have a positive blood Wassermann reaction. She readily admitted sexual promiscuity giving the name of twenty-four other contacts, twenty-two of whom were subsequently placed under medical observation. Seven of these persons were found to be infected. In addition, one of these men gave the name of a second young woman to whom he may have transmitted the infection This girl was examined, and the blood Wassermann reaction was positive

It took much time to search out all of these contacts The girl, first mentioned was below average mentality and was willing to divulge all the names of contacts

Compare this with an investigation which is being made in Syracuse

CASE 1 A colored boy, age nineteen, came to Genito-Urinary Clinic at the Dispensary He had a chancre, and the dark-field was positive When questioned regarding contacts, he denied, at first, that he had relations with anyone. Finally, he named a colored girl in Syracuse, giving her name and address He also named a girl in New York City, whom he had "picked up" on the street while visiting there. He did not know her name or address

The girl named, was examined, and found to have infectious vaginal lesions

This colored boy is receiving injections of Mapharsen every five days, and has been regular in coming for treatment

CASE 2 This girl, aged twenty-two, was named by case 1 as the source of his infection She was diagnosed as having an early, infectious syphilis, and was hospitalized at the Venereal Disease Detention Hospital

She gave the names of five men with

whom she had relations in the two months previous to the diagnosis of syphilis One of these men was her husband, from whom she is separated, and apparently had no idea of his whereabouts, therefore, he could not be examined Another man, whom she knew by his first name only, could not be located. Two of the men were examined, one had a negative Wassermann, and no signs of syphilis, the other man was positive, and is now under treatment. The fifth man was also examined, and found to have an early syphilis He is also under treatment

This investigation shows the difficulty in an urban community of locating contacts whose last names are not given and where they move from one location to another In addition there is always the reluctance of a prostitute to disclose names of contacts

No set plans are being followed for an Informational and Health Educational program Advantage is taken of every opportunity to talk to lay groups in factories, churches, clubs, and other organizations In time radio talks will probably be made by members of the Bureau The newspapers as a rule are co-operating and the words "gonorrhea" and "syphilis" are not infrequent in the news articles The Onondaga Health Association has a Social Hygiene Committee interested and cooperating in the activities of the Bureau

There has been most satisfactory co-operation from the medical profession This is evident by the number of cases reported by physicians as compared with hospitals Although no scheduled post-graduate instruction is offered, physicians are always welcome to avail themselves of the opportunities presented and a few have done so Such a course of instruction will probably be given in the near future In the College of Medicine of Syracuse University the senior students receive instructions concerning syphilis control as a part of their course in Public Health

So far as can be determined there has been no opposition to the plan by private practitioners There has been no interference between the relations of the private physicians and his patients and this is as it should be All patients who can afford to pay are referred to their own doctors

The plan has been presented to most hospital staffs in the city and it has met with favor after a free discussion of all phases of it. It is worth while to constantly remind physicians of the plans and activities because they have a right to know and such a policy assures co-operation. The *Bulletins* issued by the U S Public Health Service on venereal disease information containing reports of the latest developments in this field should be had by all physicians. Perhaps a wider distribution of these *Bulletins* will be possible in the future.

The following is an outline of the Bureau organization and activities with the facilities for epidemiological investigation and a report of the results of three months under the present plan.

Bureau of Social Hygiene A separate department of Syracuse Department of Health with its own staff and budget, directly responsible to the Commissioner of Health.

Clinical Director of Bureau—Part time

Syphilis Clinic Two services—each six months—three physicians—part time on each service.

Genito-Urinary Clinic Two services—six months each—two physicians part time on each service. Two full-time nurses, one does follow-up work. In addition, dispensary nurses available for service in clinics.

Epidemiological Personnel

- 1 Director, Physician part time
- 2 Physician part time, follow-up work with private physicians
- 3 Medical Social worker
- 4 Nurse, follow-up and clinic service.
- 5 Secretary, full time
- 6 Clerk, full time (to be appointed)

Location—Syracuse Free Dispensary

Clinics

1 Syphilis Four each week—one held in the evening

2 Gonorrhea Four each week—one held in the evening

Adjuncts of Main Clinics—Venereal Disease Hospital, mainly a detention place for infectious cases, and venereal cases from police court.

- 1 Twelve bed hospital and treatment room.
- 2 Physician—part time
- 3 Two nurses—full time.
- 4 One clerk—part time
- 5 Housekeeper—full time.

Police Court Clinic Small examining room in Matron's quarters, where women arrested for prostitution can be examined. Women found infected are either sentenced to Onondaga County Penitentiary, where they receive treatment, or given suspended sentences and receive treatment at the dispensary.

Scope of Work in 1935

1 917 patients examined in Syphilis Clinic, 730 of these on active treatment.

2 934 patients examined in Gynecological Clinic and Genito-Urinary Clinic.

3 13,296 visits by syphilitic patients, and 3,960 visits by gonorrheal patients.

4 There were 320 new patients admitted to the syphilis clinic, 30 of these were early cases.

5 In addition to above, about 150 patients were referred from Police Court for treatment.

Where Cases Come From

- 1 Referred from all clinics in dispensary
- 2 Referred from hospitals
- 3 Referred from private physicians
- 4 Referred from clinics and physicians outside of Syracuse

TABLE I—REPORTS OF VENEREAL DISEASES

	Jan (1936)	Feb	Mar	Total
Hospitals	32	57	38	127
Police Court	21	11	2	34
Dispensary	1	12	4	17
Private physicians	42	32	36	110
	96	112	80	288

MEDICAL ARTS BLDG.

New York City Plans for Combating Syphilis

CHARLES WALTER CLARKE, M A, M D, F A C P, *New York City*
 Director, Bureau of Social Hygiene, Department of Health, New York City

Aside from the action of favorable or unfavorable natural forces, the possibilities of reducing the prevalence of a communicable disease depend upon our knowledge of the disease, and on the administra-

tive practicability of measures for applying our knowledge effectively. As Hermann Biggs said, "within natural limitations a community can determine its own death rate." Syphilis is a communicable disease.

which ranks high as a cause of disability and death. Do we know enough about syphilis ever to eradicate it? If so, can our knowledge be applied practically? I believe the answer to both of these questions is in the affirmative.

As a matter of fact we know as much about syphilis as we know about any communicable disease including its etiology, pathology, course, diagnosis, treatment, and prognosis. Especially, we know how to render syphilis noninfectious and how to keep it so. If every case of early syphilis or even a large majority of such cases were found and given twenty doses of arsphenamine and forty doses of bismuth or mercury by the continuous method of treatment, the end of this disease would be in sight.

Each week, nearly a thousand newly diagnosed cases of syphilis are reported to the New York City Department of Health, over 50,000 per year but this is only a small part of the vast number in our population. If the prevalence rate of syphilis in New York City is as high as that of the United States as a whole, we must assume that there are in New York City about 378,000 cases, in other words about five per cent of the population. If we spend as much per capita for the medical and custodial care of cases of syphilis as St. Louis spends we must pay out each year about \$17,000,000 for these purposes. At present our best hope of eventual conquest of syphilis and of relief from the burden of its care appears to lie in the fact that syphilis can be rendered noninfectious by treatment. This is the foundation upon which has been built the success that has thus far been attained—success that is brilliant though limited to but a few small countries. In Denmark, a country having about half the population of New York City, syphilis has been reduced from about 700 per 100,000 in 1885 to 35 per 100,000 in 1935. Syphilis is about as uncommon in Copenhagen as typhoid fever is in New York City. In Sweden the highest prevalence rate recorded was in 1919 when an explosive epidemic carried the rate to about 600 per 100,000. In 1934 it has fallen to forty-three. Great Britain has apparently reduced the number of cases of syphilis by one-half since 1920 the highest point. In each of these countries the essential factor in achieving success appears to have been the treatment of infectious cases to render them noninfectious.

We have in New York City almost 14,000 licensed practitioners of medicine. I maintain that these physicians constitute the

shock troops in our battle against syphilis, more valuable than all the many clinics and hospitals, voluntary and official, in the city. Private practitioners collectively see or have the opportunity to see more cases of syphilis than all the institutions combined for these cases, many of them unaware of luetic infection, are visiting general practitioners and specialists for every malady to which the flesh is heir. More general use of modern diagnostic procedures, and a "lower threshold of suspicion" of syphilis would lead to the discovery of many thousand more cases of syphilis and the treatment of these cases, to the enormous benefit of the public health and the profit of the profession.

I

The immediate objective of the New York City Department of Health is to aid private physicians in discovering, treating, and controlling syphilis among patients who go to private practitioners. The practical aids which the Department of Health proposes to offer may be briefly described as follows:

1 Diagnostic Services. The Department of Health laboratory performs serologic tests for syphilis without charge, (215,000 specimens tested last year). At every one of the fourteen diagnostic centers blood specimens are taken for private physicians on request. Expert dark-field examinations and diagnostic consultations are offered in these centers, the reports being sent directly to the physicians. These diagnostic aids are available for all classes of syphilis and physicians are invited to use this service freely without fear of losing their patients.

2 Treatment Services. In order to enable private physicians to care for a larger number of patients having syphilis especially that large body of individuals who cannot pay the full regular fee the Department of Health plans as soon as possible to provide neoarsphenamine, bismuth or mercury in amounts sufficient for one year of the treatment in accordance with modern therapeutic methods. These drugs are to be supplied free upon request without distinction as to the patient's ability to pay the physician a full fee or any fee for his service. This would enable private physicians to give medical care to many patients who can pay only a small fee—fees comparable with those charged by many so-called "pay clinics." Judging from the numerous requests received by the Department of Health there are many physicians

who would be happy to treat certain patients free of charge if the necessary drugs were supplied. Because the funds when available for this purpose are expected for the present to be limited, drugs will be provided to private practitioners only for the treatment of early syphilis, syphilis in pregnancy, and congenital syphilis. Later it is hoped that the same assistance may be extended to all cases of syphilis found under private medical care. Physicians willing to cooperate with the Department of Health in the diagnosis and treatment of syphilis will be asked to report their cases at the time of requesting drugs, if they have not already done so, and supplies will be furnished in four allotments—each sufficient for three months of continuous modern treatment. Every effort will be made to supply the drugs of the physician's preference and by a system convenient for the practitioner. It should be understood that the Department of Health does not plan to require the physician to state that his luetic patient is indigent or unable to pay a fee for medical service, nor will the Department suggest any schedule of fees which the physician should charge if he uses drugs furnished by the Department. It is anticipated, however, that where a patient is able to pay the full specialist fee for medical care, the physician will not wish to administer drugs obtained at public expense.

Upon request, the services of especially selected and trained nurses will be made available to follow up lapsed cases reported by physicians, the nurse for the time being working under the direction of the physician reporting the lapsed case. This is an important feature of the plan since by sufficiently sustained treatment syphilis may be rendered permanently noninfectious and in many cases a clinical cure may be achieved.

3 Epidemiological service After a case of syphilis has been brought under treatment, the next most important duty is to answer the question, "From whom did the patient acquire the disease and to whom may he or she have transmitted it?" This in substance is the epidemiology of syphilis. In early syphilis, syphilis in pregnancy, and congenital syphilis, we have our best opportunity for epidemiologic work and many physicians in their daily practice are doing excellent case-finding work with patients of these types. The Department of Health as soon as possible will offer its services to aid the physician in finding the source of infection of the patient having early syphilis, syphilis complicating pregnancy or congenital syphilis. For this service a group of physicians will be employed and especially trained. The Department will make their

services available to physicians requesting drugs and to any other physician who wishes the cooperation of the epidemiologist in finding sources of infection and in bringing them under treatment, but in no case will action be taken without the approval of the physician with whom we are cooperating. Where this plan has been in operation about twenty-five per cent of the sources of infection have been brought under medical care, through the cooperation of the private physician and the epidemiologist.

4 Educational activities The Sanitary Code requires that every person found by a physician to have syphilis or gonorrhea shall be given a pamphlet of instruction with regard to his infection and the protection of contacts. The Department of Health furnishes this pamphlet to physicians and clinics. New editions in appropriate foreign languages are being prepared. The Department also cooperates in making postgraduate instruction available to physicians, bringing to their attention the most accepted modern ideas and methods of diagnosis and treatment of syphilis.

5 The reporting of syphilis In reporting a case of syphilis or gonorrhea or other communicable disease to the Department of Health, a physician renders a valuable public service. It would be appropriate in New York City as in Great Britain to compensate the physician for this report, and if funds were available, I should be glad to see this done. The least that the Department of Health can do, it seems to me, is to make reporting convenient and free even of the cost of postage. As soon as possible it would be desirable to provide a more convenient form for reporting, and to pay the postage upon receipt of the report. All the physicians will have to do then is to fill in the facts, slip the form into an envelope provided by the Department of Health, and deposit it in the post-box. (Reporting by initials and address is permissible and I wish to emphasize that all reports are strictly confidential, and are kept under lock at the Department of Health.) Direct reporting by physician is of great service to the Department and will be of greater service as our plans get under way, for this source of information will be taken into account in judging the progress of our fight against syphilis.

The plans discussed above are subject to modifications as the need and recommendation of physicians may indicate. We hope that these measures will help to remove the economic barriers that stand in the way of many patients who might be given medical care by private practitioners. These meas-

ures should enable private physicians to participate more fully in the attack on syphilis and bring them to the front as auxiliary health officers

II

The fifty clinics of voluntary hospitals in New York City should play a more important part in the fight against syphilis. It is proposed to aid these clinics to increase the number of indigent patients to whom they give medical care gratuitously. Many of these clinics would be willing and able to provide treatment without charge for a larger number of poverty stricken patients if drugs were supplied by the Department of Health. To clinics which charge only low fees—fees that cannot possibly compete with those of private physicians, it is desirable that the Department of Health should provide drugs to enable them to care for indigent luetic patients. In this manner, facilities are increased and brought closer to those who need them. The Sanitary Code regulates the conduct of these clinics and requires the maintenance of certain standards including adequate personnel for the follow-up of cases. After clinics have exhausted their resources in endeavoring to return lapsed infectious cases to treatment or to bring sources of infection under control, the Department of Health now employs its legal authority to seek out such uncooperative individuals and bring them under medical care. Whenever such cases are reported to the Department of Health, whether by clinics or physicians, appropriate action is taken.

III The City Hospitals

The provision of treatment for syphilis in indigents and others who cannot pay, whether this treatment be ambulatory or inpatient is primarily the function of the various tax-supported hospitals of the city. In spite of the best efforts of the Department of Hospitals and although splendid progress has been made in 1936, the facilities are still very far short of the needs of the city, especially in respect of bed accommodations. The greatest single need in New York City, it is believed, is more bed accommodation for infectious cases of syphilis and gonorrhea whether they be voluntary admissions or legally removed by the order of the Health Department. In the New York City fight against syphilis, scarcely any more important development has occurred than the provision of funds for the payment of physicians rendering

medical services in the syphilis and gonorrhea clinics of the city's hospitals. This will result, it is believed, in much more and much better service for the infected poor.

The relation of the Health authority to the City Hospital clinics is defined by the provisions of the state law and of the Sanitary Code. They provide for the follow-up by the Department of Health of lapsed infectious cases and sources of infection and give the Department power to require examination and treatment if indicated. Certain City Hospitals receive and give medical care to infectious cases of syphilis and gonorrhea removed to them by the authority of the Health Department. Neither the private physician nor the hospital, whether voluntary or official, has the authority to detain forcibly a case of infectious syphilis or gonorrhea. But by bringing such a case to the attention of the Department of Health appropriate action can be and is promptly taken for the full protection of the public health, and such cases are received by a city hospital designated by the Board of Health. More use should be made of this authority vested in the Department of Health, but more bed accommodations are needed before the laws can be used to the fullest extent for these quarantine procedures.

IV The Department of Health

We come at last to the Department of Health. Much of the work and the plans of the Department have been already described. The Department has primarily the duty of promoting, directing, and aiding the attack on syphilis as a communicable disease. As a matter of sound policy it may work through other agencies both official and voluntary to gain its ends. It must supply deficiencies. Thus for the present it is obliged to supply a part of the treatment facilities for the very poor and it now maintains seven treatment centers all of which are crowded to capacity with the unemployed and other very poor infected persons. Still more treatment facilities are badly needed but it is hoped that the larger participation of private physicians, voluntary hospitals, and the increased services of the Department of Hospitals will largely meet this need. When the Department of Health can properly close its treatment clinics it will do so, believing that treatment can eventually best be carried out in and by the city's hospitals.

No permanent service of the Department of Health is more important than that of instruction of the public with regard to

syphilis This in the future will be done to a larger extent and by better methods than in the past Diagnostic services and consultations are believed to be permanent case-finding functions, so long as syphilis remains a major health problem At present there are fourteen centers for these services The epidemiology of syphilis is a permanent obligation and the epidemiological service should be rapidly developed, for by finding and treating the infectious cases, syphilis can be brought under control

The hope of success in combating syphilis, in reducing its prevalence and mortality rates lies in full understanding and cooperation between all who are responsible for any phase of the program We cannot transport to America any European plan, successful as they may have been abroad We must draw up our own blue prints and

build our own public health structure. Useful suggestions come from a study of the Swedish Plan and equally the Danish Plan. They clearly indicate to us the fundamental scientific principles on which their success has been based But what we need for New York, we contend, is a New York Plan—one that is based on the essential medical data, but nicely adapted to our particular social and medical institutions and conditions

Without expecting miracles, but anticipating that the changes will be indicated as we progress, we believe that a start in the right direction has been made and that with the cooperation of our colleagues in private practice and in hospitals, we will, if we persevere, see a radical reduction in the prevalence of syphilis and in the disasters which it causes

THE MORE 'CURES' THE LESS CURE

Manufacturers and purveyors of patent medicines advertised as "cures" for arthritis were held up to ridicule by Dr Laurence H Mayers, professor of medicine at Northwestern University, in an address before a meeting of the American Society for the Study of Arthritis at the New York Academy of Medicine on Dec 3

Dr Mayers explained that there could be no single cure for arthritis, because there are "a thousand" causes of arthritis, and each cause requires separate treatment At the same time, he said, there are 308 trillion possible combinations of drugs, each one advertised as a "cure" for the disease The word, "arthritis," he said, means merely a bone inflammation, regardless of cause

Dr Mayers said that pure food and drug laws are effective only in keeping dangerous drugs off the market, but do not operate against the "quackery" of advertised cures He showed a neat roll of paper, on which he said he had listed the trade names of "cures" The names were typewritten, one name to a line, the lines single-spaced The list was thirty-one feet long

"If an arthritic hobbled into a drug store," he said, "and asked the clerk what he had for arthritis, the clerk could keep him standing there talking continuously for three days, two nights, seven hours and twenty minutes, and he could devote only one minute to each drug, telling the arthritic how and when to use it.

"If the arthritic should then say, 'What I really meant to ask you was what do you have to rub on the joints—I don't

want to take anything by mouth—and I haven't time to wait while you tell me about them, but just make up a sample of each preparation to rub on, and I'll send over and have these picked up as you make them,' he could keep 5,000 druggists busy working for three years preparing samples of the different kinds of liniments And he could use one-third of the ten million of the army of unemployed as messengers, that is, if he wished to finish the delivery in a year"

There is not one of these liniments, Dr Mayers said, that is of any greater therapeutic value than would be the application of a hot, wet towel to the afflicted joint. The potions to be taken by way of mouth are somewhat better, in that they give a temporary relief from pain, but none of them, he said, is a cure for arthritis

He observed that of 100 cases of sickness, eighty patients will recover naturally, eight will die in any event, and only in twelve cases can the doctor be of any assistance "A lot of arthritics get well anyway," he said, "and they will say that whatever they took last cured them"

He spoke of the old-fashioned vendor of "snake oil," who, he said, "started something" But he was an individual, and now he is incorporated, talking over broadcasting stations "to twenty-one cities through seventy-three outlets at \$18,660 an hour, to an audience of indefinite millions and he hires a symphony orchestra and several opera stars, and winds up by selling U-Rub-It instead of snake oil liniment, which was the same thing"

FAMILIAL TELANGIECTASIA WITH RECURRING EPISTAXIS

Successfully Treated With Radium, With a Review of Literature

MAN M. STERMAN, M.D. and J. COLEMAN SCAL, M.D., *New York City*

We wish to report a case of familial telangiectasia with recurrent epistaxis that was brought to our attention at the Beth Israel Hospital, and which responded remarkably well to radium therapy. Because of the rarity of this condition, we feel that a brief review of the literature on this subject is well-warranted.

Case Report

R. G., aged thirty-nine, housewife was admitted to the Beth Israel Hospital on March 19, 1934, on the Medical Service of Dr. Rothschild. Her complaint was profuse and repeated nasal bleeding.

Her family history was irrelevant. There was no definite history of "bleeders" in the family. Her parents were not blood relatives. The patient did not recall a single member of her family having been affected by a similar condition, with the exception both her parents had many "birth marks." Patient had been married eighteen years and has had three children. One boy aged seven, and a daughter, aged ten, are living and well. The daughter has been troubled with an occasional nose bleed, which she attributed to picking her nose. One child died at the age of twenty-two months of pneumonia. The patient menstruated regularly and normally, and gave no history of bleeding excessively from accidental cuts and other minor injuries sustained in her daily life.

Patient dates back the onset of the present condition to the age of nine, when she was first troubled with nasal bleeding which occurred at infrequent intervals and was of a trivial nature. These attacks gradually increased in frequency and severity, and for short intervals they recurred daily. One year ago she had a profuse nasal hemorrhage which necessitated a transfusion of five hundred c.c. of blood. On the day following the transfusion she developed a

thrombophlebitis of the left leg, which confined her to bed for about ten weeks. For the past few months the bleeding from the nose has become profuse and alarming, recurring at frequent intervals. Just prior to her admission, the patient suffered from a severe attack of epistaxis which brought her into the hospital.

Examination on admission revealed a fairly well-developed and well-nourished, although somewhat pale, middle-aged woman. Head and eyes were negative, pupils reacting to light and accommodation. Examination of the nose disclosed numerous small, ramifying blood vessels on both sides of the nasal septum anteriorly, in Kisselbach's area. These vessels stood out prominently through the thin mucous membrane, especially after the area was blanched with cotton pledgets, consisting of equal parts of ten per cent cocaine and adrenalin. At the lower anterior part of the left side of the septum, near the floor of the nose, there was a very large, wide blood vessel, the site of recent bleeding. The mouth disclosed telangiectatic spots on the anterior and dorsal run of the tongue as well as on the inner side of the left cheek. The pharynx showed several prominent dilated blood vessels, with one bleeding point visible on the left side of the pharyngeal wall. The tonsils were small, cryptic, and diseased. The ears were normal. The heart showed no enlargement on percussion, the sounds were of good quality, and no thrills were felt. There was a loud, harsh, systolic murmur heard all over the precordium with maximum intensity over the aortic area. This murmur was also transmitted to the vessels of the neck. Blood pressure was 115/70. The lungs were clear throughout. The abdomen was negative, liver and spleen were not palpable. Extremities revealed eczematous, dry, and scaly eruption of both lower legs with marked varicosities of both thighs and legs. There were several telangiectases scattered on the face,

From Medical Service of Dr. Marcus A. Rothschild and Oto-Laryngological Service of Dr. Samuel J. Kopetzky, Beth Israel Hospital

back, and abdomen, varying in size from a pinhead to a split pea. There was generalized capillary dilatation of both malar areas, giving the skin a peculiar cyanotic or purplish appearance. There was no lymphadenopathy.

Examination of the blood revealed 4,520,000 red blood cells, 5,600 white blood cells, seventy per cent hemoglobin, one per cent reticulocytes, 179,860 platelets. The bleeding time was $2\frac{1}{2}$ minutes, coagulation time $4\frac{1}{2}$ minutes, with normal clot retraction. Differential count showed fifty-six segmented, thirty-two lymphocytes, eight monocytes, one staff cell, two eosinophiles, and one basophile. Blood calcium was 9.4 mg per one hundred c.c. Blood grouping was #4. Wassermann reaction was negative. Basal metabolism was plus nine. ECG showed QRS, slurred and T_i inverted.

Consultation

Dr. Rothschild, who first saw the patient, diagnosed the condition as one of multiple hemorrhagic telangiectasia, despite any clear-cut familial history.

Dr. Kopetzky, who was called in consultation, noticed the hemorrhagic spots on the tongue and pharynx, as well as the blood clots and crusts on the nasal septum following a recent bleeding. He concurred in the diagnosis as well as to the advisability of the use of radium in this case.

Treatment

On March 28, 1934 the left nostril was cleansed and then blanched with equal parts of ten per cent cocaine and adrenalin applied for ten minutes. An applicator containing thirty-five mgm of radium element, properly screened, was then inserted opposite Kisselbach's area against the prominent blood vessels of the septum. The radium was permitted to remain in the nose for six and a half hours, giving a total dosage of 310 millicurie hours of radiation. No reaction was noted for the next forty-eight hours. On April 3, the right nostril was similarly treated with no reaction following. The patient was discharged from the hospital on April 4, with instructions to return for weekly nasal examinations. No further bleeding occurred except for a slight oozing following the removal of septal scabs.

Examination of the patient on June 26, three months later, revealed the dilated blood vessels practically gone, with Kisselbach's area blanched and smooth. There was a small area covered with a scab, which

upon removal showed a raw surface oozing blood. No further bleeding occurred.

Examination on September 28, six months after radiation, revealed the mucous membrane of the anterior part of the septum blanched, and all the vessels obliterated. Again there was no evidence of bleeding.

Comment

The bleeding in this case arose from the site of an arterial plexus formed by the junction of the inferior maxillary and the extending branch of the palatine artery. The mucous membrane in this area, Kisselbach's area, was so very thin and the veins and arteries so superficial that the slightest trauma, even sneezing or coughing was provocative enough to open them and cause bleeding. Hematological studies of this patient revealed no abnormalities which are the usual findings in these cases of epistaxis. Practically every conceivable method of treatment known had been previously used to stop this patient's bleeding, but with no success, until the application of radium which brought complete relief.

Review of the Literature

The condition of the familial telangiectasia with recurring epistaxis, known as Osler's or Rendu-Osler-Weber's disease, was first reported by Babbington¹ in 1865 in a family in five successive generations. Babbington recognized the familial nature of this affection, but did not mention in his report the underlying pathologic basis for the hemorrhagic tendency. Wilson² in a treatise on "Eruptive Angiomata" records a case of a publican who was troubled with epistaxis and bleeding from the gums, who subsequently developed "red papules" on the face, neck, hands, and arms, but fails to make mention of any family incidence. Various similar reports, notably those of Legg,³ Chiari,⁴ Chauffard,⁵ and Ullmann,⁶ call attention to this interesting condition as a form of hemiophilia. Rendu⁷ described a case of epistaxis with telangiectases with a definite family history, and referred to this condition as "pseudo-hemophilia."

Sir William Osler, in 1901⁸ and again in 1907,¹⁸ first called our attention to this condition as a distinct clinical entity.

He remarked that these telangiectases may be found on other mucous membranes and on the skin, and may be the cause of hemorrhages. Parkes-Weber¹⁶ in 1907 reported a family that presented recurring epistaxis with telangiectases and reviewed the history of eight families previously recorded. In his conclusions he emphasized that this condition affects and is transmitted equally by both sexes, that it is not associated with any hemophilic tendency, and that the angiomas are not congenital but late development defects, and that the tendency to epistaxis is present in early life long before the appearance of the telangiectases. Subsequent reviews by Hanes,^{26,30} Audry,³⁵ Gjessing,^{38,40} Steiner,^{41 a & b} Goldstein,^{46,50,57} East,⁵⁶ and Aubertin⁹² are very comprehensive and extremely illuminating.

Clinical features

It is now well-established that this condition is familial and hereditary and that the inheritance factor in this malady is a dominant one (Gossage¹⁹ and Henle⁴⁹), though atavistic skipping has been reported on several occasions.^{51,71,95} Likewise it has been definitely shown that both sexes are equally affected, and that its transmission is not sex-linked,¹⁰ with perhaps a slight preponderance in females.⁵⁶

The various blood findings, such as bleeding time, coagulation time, clot retraction, blood calcium, platelet count, white blood cell and differential count, and erythrocyte fragility tests are within normal limits.^{16,51,96} A hypochromic anemia is usually found and the degree is dependent upon the severity and duration of the bleeding. In many cases the anemia has been quite marked and troublesome,^{7,8,35,86,90} and not infrequently has resulted in death.^{5,14,17,20,42,74,80,105} When the bleeding has been profuse, the usual concomitant symptoms, such as, weakness, dyspnea on exertion, palpitation, vertigo, fainting, and edema of the legs, are invariably encountered. Most authors stress that the nasal bleeding usually begins at the end of the first decade and that the telangiectases do not become visible until about the middle of

the third or fourth decade,^{16,35,80} Erdheim,⁹⁹ on the other hand, maintains that in over fifty per cent of the cases the telangiectases appear at an early age. In our case the patient was first troubled with epistaxis at the age of nine.

The nasal bleeding is by far the most frequent and annoying feature that is encountered, it is not the only one. Cases of profuse and repeated hemoptysis^{45,50,111} hematemesis^{8,74,84,95,97} hematuria^{9,12,32,56,64} intestinal and rectal bleeding,^{24,39,42,68,74,75,84,98} and hemorrhages into the central nervous system,^{48,59,80,89} with or without associated epistaxis have been reported in familial and hereditary telangiectasia. Of course, it must be admitted that several of the above citations are not true examples of this clinical syndrome inasmuch as either one or another of the cardinal features is lacking. Nevertheless, their inclusion is justifiable since atavistic forms of this affection have been frequently found. The fact that telangiectases have not been found in some of the cases cited above does not necessarily exclude them from this clinical group, as minute angiomas may very readily be overlooked in parenchymatous organs, such as kidneys or lungs.

The blood grouping of four cases reported by Fitz-Hugh⁵ were found to belong to group "O" or type IV (Moss). This author states that individuals who present an associated hepatosplenomegaly develop an increasing intolerance to transfusion in the form of "post-transfusion jaundice," and cites two incidents of death following its use. Van Bogaert¹⁰² concurs with these findings. Adant¹⁰⁰ in his report of three cases found the same type IV in all. In our case too, the blood group was type IV.

Recently Fitz-Hugh⁵ and others^{66,72,80,102} have observed an associated enlargement of liver and spleen, particularly in those patients who have been suffering from repeated and prolonged hemorrhages. Van Bogaert¹⁰² is of the opinion that the hepatosplenomegaly constitutes an integral part of the clinical entity, and is not the result of repeated hemorrhages. Marked varicosities of the legs and thighs^{16,31,67,72,90} and the presence of hemorrhoids^{8,28,32,76,92,97,103} have been frequently observed in the more

advanced stages of this affection Adant¹⁰⁷ believes that the anomaly of spina bifida found in his case is analagous to the developmental defect of the blood vessels. Cases presenting visceroptosis and hernias have been observed in this condition.^{97 109} The presence of a systolic murmur in the absence of any marked degree of anemia has been previously reported on many occasions.^{10 41a 68 81b 89 95} In our case the murmur was quite striking and unusual in quality. In view of the absence of any luetic or rheumatic history and without any definite evidence of arteriosclerosis we ventured to regard it as a result of an inherent developmental valvular defect analogous to the vascular maldevelopments. At any rate, we feel it deserves mention and further observation.

Pathology

The histopathology of the lesions in hereditary telangiectasia has been described by Hanes,²⁰ Gjessing,⁴⁰ Arrak,⁶³ and others.^{67 99} It consists essentially of a developmental defect in the vessel wall and menenchymal tissue of the skin and mucous membranes. The venules and capillaries constituting these telangiectases are dilated and thinned out, being lined by a single layer of endothelium interspersed with a single stratum of connective tissue protruding just under the corium. The papillae and the usual undulations of the stratum germinativum are obliterated. The muscular and elastic layers of the vessel wall are conspicuously deficient. These angiomas vary in size from a pinhead to a split pea and may be punctiform, nodular or of spired variety. They are found mostly over the nasal septum (Kisselbach's area), lips, cheeks, eyelids, scalp, tongue, particularly dorsum, tip and edges, gums and other parts of the buccal mucous membranes, and to a lesser extent over the trunk and extremities. On the finger tips their site of predilection is under the nail bed.^{5 10 25 37 42 69 89 97} Angiomas have also been found in the stomach,⁸ bladder,^{66 94 100} kidneys, respiratory organs (larynx,^{10 92 103} bronchi,⁵¹ and vocal cords^{94 106}), lower bowel,^{84 100} brain and liver.^{84 100} They bleed very readily following the slightest trauma,

and at times without any provocation.²² A severe and profuse epistaxis has been known to follow a mild sneezing, coughing or blowing of nose. Occasionally a change in weather conditions has been found to be the cause of sudden nasal hemorrhage.

Differential diagnosis

The diagnosis of hereditary hemorrhagic telangiectasis is, as a rule, not difficult. The disease with which it is most often confounded is hemophilia. As a matter of fact, several of the original reports were classed in this category.^{3 4 5 6} It can easily be differentiated from hemophilia by the normal coagulation time and by its occurrence in either sex. From purpura it is differentiated by the normal bleeding time, normal clot retraction, negative tourniquet test, and normal platelet count. Cases that present hematemesis, hemoptysis, melena or hematuria may occasionally be confounded with diseases of those organs, such as, tuberculosis, malignancy, etc. In these cases a careful history and the finding of telangiectases have proven helpful in diagnosing this condition. Occasionally it has been mistaken for pernicious anemia⁷¹ and subacute bacterial endocarditis.¹⁰¹ Here again, the nature of the spots, the history of familial incidence, the negative blood findings, and the absence of the cardinal symptoms of those diseases will readily exclude them.

Treatment

The treatment of this affection resolves itself principally to the arrest of bleeding wherever it may occur, and if the anemia is marked, stimulation of the bone marrow is indicated. The use of coagulants, such as calcium, gelatin,³⁰ peptone intramuscularly,¹⁰⁰ cobra and rattlesnake venom¹⁰⁵ and other drugs and sera, long advocated, is without any rationale and of no value, since it has been definitely established that this affection is a hereditary maldevelopment of the vascular apparatus. The administration of iron, arsenic, and liver extracts for the anemia is of value, and its use is, of course, purely symptomatic. Blood

ransfusion is of decided but only temporary benefit when the anemia is marked and the general condition becomes grave

The treatment must primarily be directed toward the destruction or removal, if possible, of the bleeding angiomata. In cases of epistaxis various forms of chemical^{20 44 55b 81a 108} and electrical^{14 15 22 34 63 70} cauterization have been employed, but with only slight or temporary improvement. The application of chromic acid bead and other forms of chemical cautery, such as trichloroacetic acid^{81a 108} and carbon dioxide snow,^{76 78} have proven successful in temporarily stopping the bleeding, but recurrence of hemorrhage has been the rule. The same holds true for cauterization by means of the electric needle. Occasionally cauterization has even been found to aggravate the bleeding.^{83 84} The use of the rubber bag inflation plug recommended by Hurst and Plummer⁸⁴ is of value as an emergency tamponade or preliminary to radiotherapy. Van Wagenen³⁶ reported favorably upon the use of thrombokinasin intranasally as a local hemostat. The application of an oil spray intranasally is of decided benefit in preventing hemorrhages and removing crusts.

The reports about the use of radium in this condition appear more promising. Paul⁴³ reported upon its use stating that the "epistaxis has been greatly

minimized." Mackay and McKenty⁵⁸ have applied it in two cases with apparent success. Hicks and Knox⁸² used it in one case and have reported an amelioration of symptoms, the bleeding having become "much less frequent and much less severe." Plummer⁸⁴ reported definite but only temporary improvement following its use. In our case the beneficial result following several radium applications was quite striking. We feel, therefore, that the use of radium in hereditary hemorrhagic telangiectasia is an invaluable asset in our therapeutic armamentarium, and to all indications may prove to be the treatment of choice in this affection.

Summary

1 A case of recurring epistaxis with multiple telangiectases in which radium treatment has shown a marked amelioration of symptoms is reported.

2 The finding of an unusual cardiac murmur is pointed out, and the possibility that it may be an inherent valvular developmental defect is suggested.

3 A historic resume of hereditary hemorrhagic telangiectasia is given, the salient pathological and clinical features are discussed, and the various therapeutic measures are briefly reviewed.

LITTLE KNOWN FACTS ABOUT INHERITANCE

Racial coloring is inherited as a "dilution" character. There is no possibility of a "throw-back" to a pure black as popularly supposed.

As the geneticist understands inheritance a bacterially-caused disease is never inherited. Syphilis may infect the embryo or fetus and the child may be born syphilitic. Tuberculosis may infect the child at or immediately after birth. In neither case, however, is this inheritance.

Skin patterns, that is, fingerprints, hair whorls, etc., are inherited probably as "mosaic" patterns.

Blood groups are inherited apparently in a Mendelian or unit-character fashion.

In human cells, notably those of the salivary glands, the "genes" or carriers of unit characters within the chromosomes

have actually been seen.

Geneticists believe that hereditary factors are the most important ones in the cause of cancer. Yet the person does not inherit cancer. He inherits characters which pre-dispose toward tumor formation, toward certain types of tumors and toward tumors arising in certain organs. Without these inherited characters true tumors will never develop. With them a myriad of intrinsic causes will incite to the beginning of tumors, malignant or otherwise.

Body-build, constitution etc while inherited, are probably transmitted through the endocrine system.

Form, texture of teeth, jaw-size are all inherited, but not always from the same forebear, which probably accounts for most malocclusions.—*Illinois Medical Journal*

VASOMOTOR RHINITIS

C STEWART NASH, M D , *Rochester*

Rhinitis is fundamentally a disease of civilization, infrequent and simple in atavistic races but increasingly frequent and complex as a social system develops

Animals in their native haunts are seldom the victims of nasal catarrh, but captive and domestic animals are "A hundred years ago Rarotonga was a flourishing heathen country where cannibalism was the fashion, murder of shipwrecked sailors a common custom, and raids upon neighboring islands the chief diversion. Today, no longer cannibal, no longer warlike, but hospitable, it has learned to wear white man's clothes, to eat white man's food, to catch white man's colds and die of chest diseases" Less ferocious, but no less affected is Tahiti, and both by the introduction of factors making them more susceptible to rhinitis have become so involved in its complications that racially they are doomed to extinction

Stefansson lived with the Arctic Eskimos for nine years without encountering colds. When provisions were supplied from civilization, however, rhinitis became common. Certain groups of Japanese peasants whose chief food consists of fish and sea plants are noticeably more immune to rhinitis than their inland neighbors. Is civilized man responsible for this disease? Is there something lacking in the artificial environment of society that the primitive peoples formerly possessed?

We recognize that a rhinitis may be infectious or noninfectious, and we assert that both these conditions are infrequent in primitive races but common in modern man. We further maintain that this holds true whether the individual lives in the polar regions and clothes himself in furs or dwells in the tropics and exposes his body to the sun. Civilization apparently brings with it a susceptibility to rhinitis, and the more specialized society becomes, the more complex the rhinitis. If this assertion applied to infectious

types only, it might be contended that civilization in its effort to help uncivilized peoples directly infected them, but vasomotor rhinitis, infrequent among savages and prevalent in modern civilization, is not contagious. Infection does not appear to be the sole explanation.

Civilization implies refinement, a highly organized society, individual adjustments, and competition. The result of this is the reclamation of the race from savagery, the one thing which apparently protects it from rhinitis. Savagery implies brutality, cruelty, and ferocity, which may or may not be protecting agents against nasal catarrh, but it also implies primitive food and natural habits of living. If the savage traits are the protecting agents, then the immunizing factor is probably adrenalin, their common denominator. But how does the savage acquire this extra adrenalin or the stimulus to produce it?

The barbarian eats meat, raw and cooked, he prefers the nonmuscular portions, particularly the liver, adrenals, and kidneys, he recognizes blood as an essential part of his diet, the fibrin being cooked and the defibrinated portion divided sparingly among the group. Milk, preferably from animals grazing in green pastures, green vegetables, particularly sea weeds, and an abundance of fish are considered essential constituents of the tribesman's diet, and he thrives on it. He also leads a simple social existence. Something protects him against rhinitis.

Civilization, on the other hand, gives us polished rice, branless wheat flour, refined sugar, highly specialized cereals, an appetite for muscular meat rather than the endocrine bodies, and the flesh of castrated animals in which the transfer of animal vigor into the human is sacrificed. Milk is produced for its quantity or fat content and not according to the amount of organic iodine, phosphorus, and other minerals that it might contain, and

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 28, 1936*

then in addition it is pasteurized Pastries, confections, and starches complicate the menu Vegetables are raised for size and appearance and not their mineral content, and sea weeds, nature's own formula, are infrequent items of diet Our contempt for raw meat and blood may be well-founded parasitically but the savage has great faith in their virtues Civilized man leads a complex social existence Something makes him susceptible to rhinitis

Rhinitis is an inflammation of the nasal mucous membrane, primarily infectious or primarily noninfectious The noninfectious type may become secondarily infected and any or all sinus membranes may simulate or complicate the nasal inflammatory process A long continuance of either of these types results in mucous membrane changes which, by the character of the alteration, identify them as chronic forms of rhinitis, namely the hypertrophies, the hyperplasias, the polyposes, etc These, however, are not the direct result of one's habits of living but the sequelae of a pre-existing rhinitis

This paper recognizes the association between civilization and the frequency of infectious rhinitis, but will limit itself to the noninfectious or vasomotor type

Dorland defines vasomotor as "presiding over the movements of the walls of the blood vessels, that is, their contraction or expansion, or any agent or nerve that effects vasomotion" Noninfectious or vasomotor rhinitis, then, is a pathological condition produced by some agent which causes the vessels of the nasal mucosa either to abnormally constrict or abnormally dilate By definition, then, the term vasomotor rhinitis cannot be used synonymously with nasal allergy or allergic vasomotor rhinitis which is fundamentally a vasodilator disease, but it must also include the vasoconstrictor diseases such as atrophic rhinitis, rhinitis sicca, and ozena, which have been classified as a Raynaud's disease of the nose

We shall further limit this paper to a study of the vasodilator form of rhinitis The exciting cause of this disease is understood, it is a substance inhaled or ingested which is irritating to the nasal mucosa Why certain substances are violently irritating to one individual and apparently nonirritating to another, or why the same membrane may after years

of normality become highly sensitive, has not been satisfactorily explained The hereditary factor is an observation, not an explanation In any case, some irritating agent produces a hyperfunction of the mucosa, and whether the reaction is mild or violent determines its nomenclature but not its basic etiology Probably the simplest form of noninfectious rhinitis is the onion irritation, its cause is obvious, its cure simple Similarly we could classify wood smoke and chemical inhalants The food irritant, however, is less obvious but no less important Violent reactions, caused by such allergins as fish or cocoa nut, produce symptoms anyone can interpret, but lesser vasodilator reactions, perhaps complicated by a secondary infectious process, present real problems that have to be detected

Excessive candy eaters often have a vasodilator rhinitis One such individual, a girl of nine years, was treated for six and a half years by a rhinologist for sinusitis without material benefit Total abstinence from candy relieved all symptoms and she has been well for four years In other instances, large quantities of white bread eaten over an extended period of time produced the same condition Irish potatoes, macaroni, citrus fruits in overabundance, will occasionally result in a vasodilator rhinitis Even the nasal catarrhs are often traceable to these causes It is possible, of course, that specific allergins may have produced these reactions

There is within a few miles of the city of Rochester (New York) an experimental farm on which are raised vegetable food stuffs and various animals such as horses, cows, pigs, sheep, and dogs Although most of the animals are herbivorous, rhinitis (which is only an incidental observation) can be produced by overstepping the animal threshold of tolerance for starches and sugars Conversely, the rhinitis can be relieved by their control or by raising the threshold of tolerance by the ingestion of organic and inorganic minerals in superabundance Such an experimental farm is unnecessary for our purpose, however, for the rhinologist's and allergist's offices provide better experimental laboratories

The most complicated form of the noninfectious type is the allergic vasomotor

rhinitis. Animals and primitive races do not suffer from such allergins as orris powder, soaps, or wheat flour, for obvious reasons. But why is it that hay fever, so common in this country, is less common among the uncivilized? The pollens are certainly present in the tropical regions.

With these thoughts in mind, how should a vasodilator rhinitis be managed? Briefly, we suggest the following:

1 Study the mucous membrane, particularly as to color. Jarvis has contributed much to the solution of this problem and his studies on nasal mucosae should be familiar to every rhinologist.

2 Assume that all rhinorrheas are vasodilator in origin until proved otherwise.

3 Bear in mind that an infectious rhinitis may occur in a susceptible membrane and anything done to increase resistance is good therapy anyway.

4 In long-standing cases, treat the complications only long enough to give the patient symptomatic relief. Recognize the fact that you are treating the complication and not the disease.

5 Attempt to remove the exciting cause. In this the allergist is both a comfort and a disappointment, but a common understanding between him and the rhinologist is a distinct aid to the patient. Pollens, common inhalant irritants, and common food susceptibilities are readily detected and may be treated by exclusion, desensitization, etc.

6 Relieve the patient. In the complex forms, that is, the allergic vasomotor rhinitis, this is particularly important. Local applications of adrenalin, ephedrin, and cocaine give temporary relief, other topical measures, in my experience, make the patient worse. Hay fever, if not controlled by pollen desensitization, change of environment, or some other procedure which works sporadically, has either to be endured or treated heroically. Warwick's method of ionization may be heroic, but in uncomplicated fully developed hay fever it does produce, in a significant percentage of instances, satisfactory results. The use of concentrated silver nitrate or carbolic acid on the mucosa is too indelicate for my nature. In the perennial type, I have employed cauterization of the sphenopalatine ganglion and obtained satisfactory results in a large number of cases. Drug therapy is occasionally effective. Ephedrin, atropine, or amytol and ephedrin, adrenalin, or calcium may be used. In the less acute cases it is my experience that dilute nitrohydrochloric acid is often effective.

7 Obviously, a noninfectious vasodilator rhinitis is caused by some irritant. Not so obvious is the fact that underlying this is something which controls one's susceptibility to these irritants. That something is apparently present to protect the atavistic types but disappears as civilization develops. The unproved assumption is that man in his effort to make life more abundant has lost nature's protection against rhinitis and, furthermore, that he is apparently insulting his nasal mucosa by overstepping its threshold of tolerance for certain types of food which in their unrefined forms could not be taken in such quantity as to produce this condition. Management of all cases should be carried out with this in mind. Elimination diets and experimental adjustments in social stabilization should be tried in an effort to restore nature's immunity against rhinitis.

Conclusions

1 Vasomotor rhinitis is primarily a noninfectious disease which may become secondarily infected.

2 The term vasomotor rhinitis properly employed includes both vasoconstrictor and vasodilator diseases and therefore cannot be used synonymously with allergic vasomotor rhinitis.

3 The following assumptions are made:

a Vasodilator rhinitis is frequent among civilized peoples.

b Vasodilator rhinitis is infrequent among primitive peoples.

c All factors considered, it seems probable that organized society in its process of development has removed from its food certain elements which contain some of nature's protection against rhinitis, or perhaps society itself is a factor. In any case, the primitive races still have this protection.

d An effort should be made to find out what is wrong in the patient's habits of living and change it, and further to correct any abuse to his membranes from an overabundance of untolerated food.

4 Routine symptomatic treatment of this disease should be continued but supplemented by experimental procedures.

5 The purpose of this paper is not to promote any one theory as to the cause of vasomotor rhinitis but to encourage further studies in the biologic, psychic, and social aspects of that disease.

ACUTE OBSTRUCTION OF THE CENTRAL RETINAL ARTERY

Relieved by Intravenous Sodium Nitrite

BENJAMIN ESTERMAN M D, *New York City*

Sudden total blindness in one eye due to obstruction of the central retinal artery is almost always sufficiently terrifying to send the patient to the nearest physician without delay

The usually accepted forms of treatment for this have been inhalations of amyl-nitrite, vigorous massage of the eyeball, and as a last resort, paracentesis of the anterior chamber or some variation of this such as iridectomy or sclerotomy, in an attempt to restore circulation by the sudden diminution in intraocular tension. Potassium and sodium tartrate has also been employed to gain this end by dehydration, and in later stages potassium iodide has been used to promote absorption of clots, usually too late to restore useful sight

Pilocarpine¹ or dionin² or the two combined have been instilled into the conjunctival sac in attempts to increase circulation, and one worker reported a good result following retrobulbar injections of 0.3 to one c.c. of 0.1 per cent atropine sulphate in a case which was probably due to angiospasm³

More recently, reports have been published of the use of acetyl-choline as a retinal vasodilator^{4, 5} and Orr and Young⁶ (1935) reported marked success from the injection of acetyl-choline subconjunctivally in two cases, in one of which an embolism was definitely seen to be dislodged

The neurosurgeon Pieri⁷ has reported favorable results in recurrent retinal angiospasm after section of the cervical sympathetic in four cases, one of which he was able to follow for two years without a recurrence

The following is a report of a case in which sodium nitrite* solution was injected intravenously to cause marked

vasodilatation with restoration of retinal circulation in a few minutes and normal vision within the hour

Case Report

F E, male, aged forty-two, was admitted to the service of Dr Knapp at the Herman Knapp Memorial Eye Hospital on Oct. 21, 1934 with a complaint of sudden loss of vision in the left eye fifteen minutes previously. He had already been to the emergency room at the Roosevelt Hospital where he had been given amyl nitrite inhalation with no effect

The right eye was normal. The left eye had barely light perception, light projection was absent. The pupil was moderately dilated and scarcely reacted to direct light. Ophthalmoscopic examination showed an occlusion of the central retinal artery, whose branches on the retina were narrowed and empty except for occasional bits of blood column moving in a reverse direction. The veins were normal. The retina proper had the grayish-pink color of beginning edema with the macula a brighter color, the forerunner of the cherry-red spot to come. Intraocular tension was normal and blood pressure 144/96

There was no history of previous visual disturbance, nor was there evidence of cardiac or venereal disease or blood dyscrasia.

Another inhalation of amyl nitrite was given and vigorous massage of the globe was started, without much success or change in the ophthalmoscopic picture

A few minutes later 200 mgm of Nitroscleran (Tosse) was given intravenously. (This was more than the usual dose, but given in this case because the man was unusually large and well-built in the ordinary sized person one should give 150 or 100

*The solution used is marketed by Tosse under the name Nitroscleran and contains in ampules, Sod. chloride 0.6%, di-sod. phosphate 0.35%, di-potass phosphate 0.2%, Sod nitrite 10.0%. Each ampule contains one c.c. of solution

(mgm.) Within three minutes the patient began to feel the symptoms of mild shock, and blood pressure dropped to 80/60. Immediate ophthalmoscopic examination showed all arteries to be filled and almost twice the normal caliber, with retinal edema and macular blush gone.

After a short rest period, vision was found to be 20/20+ in the affected eye with a normal peripheral field. Blood pressure had returned to 110/74, and the patient was given nitroglycerin tablets gr 1/100 (0.6 mgm.) to take every four hours and allowed to go home.

He was observed daily for three months with no return of the ocular symptoms except that on two occasions small superficial boat-shaped hemorrhages with clear centers appeared not far from the disk and each was resorbed in about ten days—leading to the suspicion that the original attack might have been true embolism instead of angiospasm. However, all relevant medical and laboratory examinations were negative. In June 1935 the patient ceased coming to the clinic and we are assuming that had there been a recurrence he would have returned.

It should be remembered that there are undoubtedly cases of retinal vascular obstruction (if due to angiospasm) which clear up spontaneously. However, the damage to retinal tissue from ischemia makes it imperative that retinal circulation be restored as soon as possible, even if this means surgical intervention.

The treatment by intravenous sodium nitrite in this type of case is rational because

1. Where, as described above, both amyl nitrite and massage fail, this treatment may enable us to avoid an operation,

2. Even though it is usually impossible by ophthalmoscopic examination to distinguish between obstruction due to embolism and that due to spasm, a powerful vasodilator is indicated in either case—to counteract the

spasm or to enable the embolus to lodge further along in the arterial tree where it will do less damage,

3. Nitrocleran is apparently safe. It has been used for a number of years, especially abroad, in treating vascular hypertension. In 1930 Pfimlin¹ reported fifteen cases who had been given small doses (20–40 mg.) intravenously twice weekly, a total of 177 injections without mishap, in the treatment of tobacco amblyopia. Similarly Duggan² in a very careful study, reports a total of 324 injections in thirty-four patients with tobacco amblyopia (100 mg. doses intravenously, daily or every other day) without mishap.

4. While it is felt that subconjunctival injection of acetyl-choline³ is probably a better method because it is given locally, probably the only ones who will use this will be ophthalmologists. Not many general practitioners will risk giving subconjunctival injections. On the other hand, where the treatment can be given intravenously, it can be administered by the general physician as soon as the diagnosis is established, thus saving valuable time.

A case of occlusion of the central retinal artery is presented, which the author had the unusually good fortune to see within fifteen minutes of onset. Intravenous sodium nitrite is offered as a quick and safe means of overcoming this condition by the general practitioner, where time is an important factor, and where an ophthalmologist may not be readily available.

TO SHOW WHAT IS 'ON FOOT'

In the lobby window in the Annex Building of Marshall Field and Company is an exhibit on "feet" designed to show that foot disorders are frequently traced to systemic diseases and emphasizing that the family physician should be consulted before any corrective measures are introduced, says the *Illinois Medical Journal*. Models are displayed to show that a shoe should be

made to fit the foot rather than the foot to fit the shoe. There is also a model in plaster of the perfect foot of a child. This window has been given to the Chicago Medical Society, free of rental and service charges, for the display of health educational material. The material is prepared by the educational committee of the Illinois State Medical Society.

TREATMENT OF PSORIASIS BY COLLOIDAL MANGANESE

Review of Literature and a Report of Seventy-Two Cases

HENRY D NILES, M.D., *New York City*

From the Skin and Cancer Unit, New York Post Graduate Medical School and Hospital, Columbia University

Colloidal manganese was first used in the treatment of psoriasis in 1922 by James Moore¹. He had two patients with chronic staphylococcus infection and marked psoriasis in both of whom the psoriasis improved greatly after six injections of staphylococcus vaccine, but showed no response to six more. Because of the early response to the vaccine and on account of the reports of the beneficial effect of manganese on staphylococcus infections, Moore then treated these patients with colloidal manganese. One was entirely well after four injections and the other after eight. He later treated a total of thirty-five psoriatic patients with colloidal manganese. He gave two doses of one-half c.c. each, intramuscularly at four day intervals and then one c.c. weekly until the eruption disappeared. His conclusions were as follows:

Psoriasis is improved, although not completely cured, by staphylococcus vaccine but it may be cured by six to sixteen intramuscular injections of colloidal manganese without any local treatment, because of the action of staphylococcus vaccine and especially colloidal manganese and on account of its resemblance to a chronic staphylococcus infection, psoriasis may be due to a special staphylococcus.

Although one may not agree with Moore's conclusions, according to his theory, his use of manganese for psoriasis was logical.

The next report on the treatment of psoriasis with colloidal manganese was made by Richter^{2a} in June 1930, before the Berlin Dermatological Society. He used a preparation called psorimangan. This was given intramuscularly twice a week in doses of one c.c., gradually increasing to four c.c., for a total of ten

to sixteen injections. He treated twenty six patients without any local applications and obtained excellent results in twenty. He considered that the poor results in the other six patients were due to too small dosage, necessitated by the sensitivity of these patients to the drug.

At a later meeting of the same society, Richter^{2b} presented a patient with extensive psoriasis of fifteen years' duration who was cured with manganese. He also mentioned another case in which complete healing occurred six weeks after stopping the injections, although they appeared to have no effect during the course of treatment. For six years, this patient had been treated unsuccessfully with many other methods. In the discussion, Pinkus stated that many times the results with manganese are very good and also many times completely negative. He obtained the same results with different preparations and they were all well-tolerated, but recurrences appeared early and frequently. Langer reported fifteen cases in which he had good results, especially when the injections were combined with ultra-violet radiation.

Schmidt's³ results and conclusions were very different from those of Moore and Richter. He treated eleven patients with a total of fifteen to twenty injections of psorimangan but none were cured until after the addition of local therapy. The drug was given intramuscularly twice a week, starting with one c.c. and increasing the dose to three to four c.c. after four or five injections. Very severe general reactions and marked local pain occurred with both low and high doses. The only favorable effect was paling in the centers of the lesions and the injections did not prevent rapid recurrences. The

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 29, 1936

lesions did, however respond more rapidly to salves containing chrysarobin after the injections than they had before. Schmidt thought that the increased oxidation, which has been found to be caused by manganese, might have made the lesions more sensitive to chrysarobin or that the manganese might have acted as a foreign body or fever therapy, through an inflammatory process and an absorption of destroyed body protein. On account of the absence of any marked favorable effect, and because of the severe general reactions and local pain, Schmidt concluded that colloidal manganese, in its present form and dosage, was not suitable for the treatment of psoriasis and had no advantage over chrysarobin, but that protracted treatment with small doses, alone or combined with local measures, or a different, less toxic, preparation might give better results.

Abramson⁴ at a meeting of the North German Dermatological Society in May 1931, reported on twenty patients to whom he had given bi-weekly almost entirely intramuscular injections of psorimangan. He started with doses of one c c and later used two to three c c. There were no reactions except occasional transient fever and some local pain. He found that the healing from the combined treatment with psorimangan and one-half per cent cinolin-vaseline was definitely quicker than with the salve alone and stated that up to that time, he had observed no failures in the combined treatment.

Two months later, Szego and Von Luka⁵ reported their results in twenty-seven patients who received twelve to sixteen intramuscular injections of the same drug in doses of one-half to two c c once or twice a week. They preferred the intramuscular injections to the intravenous because the latter caused febrile reactions which required hospitalization. All their patients also had local therapy. Sixteen were completely healed, and eight partly, the remaining three proved refractory. None were made worse and there were no new lesions. The healing effect began after six or eight injections and the time required for the disappearance of the lesions was two months less than with topical remedies alone. Nine months after stopping the treatment, there was no

recurrence in any of the sixteen who were completely healed, but there was a new eruption in two of the eight who were partly improved. In both patients, this disappeared after a few more injections. These authors concluded, "the comparatively great number of cures, as well as the absolute safety of the treatments, assures to psorimangan an important role in the battle against psoriasis."

Schwarz⁶ reported his experience with colloidal manganese in the treatment of a man with extensive psoriasis. In four weeks, this patient received nine intramuscular injections, starting with 0.5 c c and increasing every three days by 0.5 c c up to four c c. At the fourth injection, he complained of severe local pain, anorexia, fever, and weakness. A different lot of the drug was used, but, after four more injections, the treatment was stopped because of visual disturbances, obstipation, oliguria, hematuria, and severe local pain. All of these disappeared entirely two days later. The scales ceased forming and the skin became flat with only dark pigmentation remaining but there was an early recurrence. Schwarz admitted that the patient should have received at least sixteen injections, but he concluded that, on account of the severe general reactions, manganese was too dangerous to use in a benign condition like psoriasis.

Bolnstedt⁷ discussed the reason for the use of manganese in psoriasis. This rests on the investigations of Bloch, Meirowsky, Konigstein, and Van Kerchoff, who found a constant decrease in the oxidative function of the epithelial cells in the scales of the psoriasis papule. Van Kerchoff believed that this oxidational process could exist without an organic ferment. Von Herman found that treatment of psoriasis with manganese was followed by considerable increase in the residual ash of the skin and concluded that manganese was deposited in the skin. In five out of six cases through measurements of the anaerobic glycolysis, Warburg discovered a definite rise of lactic acid production after the intravenous administration of two c c of psorimangan. Because of these findings, Van Kerchoff, Pautrier, and Lauromier considered that colloidal manganese, acting as a catalytic agent, increases fermentative oxidative

TREATMENT OF PSORIASIS BY COLLOIDAL MANGANESE

Review of Literature and a Report of Seventy-Two Cases

HENRY D NILES, M D, *New York City*

From the Skin and Cancer Unit, New York Post Graduate Medical School and Hospital, Columbia University

Colloidal manganese was first used in the treatment of psoriasis in 1922 by James Moore¹. He had two patients with chronic staphylococcus infection and marked psoriasis in both of whom the psoriasis improved greatly after six injections of staphylococcus vaccine, but showed no response to six more. Because of the early response to the vaccine and on account of the reports of the beneficial effect of manganese on staphylococcus infections, Moore then treated these patients with colloidal manganese. lesions did, however, respond more rapidly to salves containing chrysarobin after the injections than they had before. Schmidt thought that the increased oxidation, which has been found to be caused by manganese, might have made the lesions more sensitive to chrysarobin or that the manganese might have acted as a foreign body or fever therapy, through an inflammatory process and an absorption of destroyed body protein. On account of the absence of any marked favorable effect, and because of the severe general reactions and local pain, Schmidt concluded that colloidal manganese, in its present form and dosage, was not suitable for the treatment of psoriasis and had no advantage over chrysarobin but that protracted treatment with small doses, alone or combined with local measures, or a different, less toxic, preparation might give better results.

Abramson⁴ at a meeting of the North German Dermatological Society in May 1931, reported on twenty patients to whom he had given bi-weekly almost entirely intramuscular injections of psorimangan. He started with doses of one c.c. and later used two to three c.c. There were no reactions except occasional transient fever and some local pain. He found that the healing from the combined treatment with psorimangan and one-half per cent cignolin-vaseline was definitely quicker than with the salve alone and stated that up to that time, he had observed no failures in the combined treatment.

Two months later, Szego and Von Luka⁵ reported their results in twenty-seven patients who received twelve to sixteen intramuscular injections of the same drug in doses of one-half to two c.c. once or twice a week. They preferred the intramuscular injections to the intravenous because the latter caused febrile reactions which required hospitalization. All their patients also had local therapy. Sixteen were completely healed, and eight partly, the remaining three proved refractory. None were made worse and there were no new lesions. The healing effect began after six or eight injections and the time required for the disappearance of the lesions was two months less than with topical remedies alone. Nine months after stopping the treatment, there was no

recurrence in any of the sixteen who were completely healed, but there was a new eruption in two of the eight who were partly improved. In both patients, this disappeared after a few more injections. These authors concluded, "the comparatively great number of cures, as well as the absolute safety of the treatments, assures to psorimangan an important role in the battle against psoriasis."

Schwarz⁶ reported his experience with colloidal manganese in the treatment of a man with extensive psoriasis. In four weeks, this patient received nine intramuscular injections, starting with 0.5 c.c. and increasing every three days by 0.5 c.c. up to four c.c. At the fourth injection, he complained of severe local pain, anorexia, fever, and weakness. A different lot of the drug was used, but, after four more injections, the treatment was stopped because of visual disturbances, obstipation, oliguria, hematuria, and severe local pain. All of these disappeared entirely two days later. The scales ceased forming and the skin became flat with only dark pigmentation remaining but there was an early recurrence. Schwarz admitted that the patient should have received at least sixteen injections, but he concluded that, on account of the severe general reactions, manganese was too dangerous to use in a benign condition like psoriasis.

Bohnstedt⁷ discussed the reason for the use of manganese in psoriasis. This rests on the investigations of Bloch, Meirowsky, Konigstein, and Van Kerchoff, who found a constant decrease in the oxidative function of the epithelial cells in the scales of the psoriasis papule. Van Kerchoff believed that this oxidational process could exist without an organic ferment. Von Herman found that treatment of psoriasis with manganese was followed by considerable increase in the residual ash of the skin and concluded that manganese was deposited in the skin. In five out of six cases through measurements of the anaerobic glycolysis, Warburg discovered a definite rise of lactic acid production after the intravenous administration of two c.c. of psorimangan. Because of these findings, Van Kerchoff, Pautrier, and Lauromier considered that colloidal manganese, acting as a catalytic agent, increases fermentative oxidative

processes in the epithelial cells and thus helps disturbances of these in psoriasis.

Bohnstedt found the intramuscular injections too painful to continue but there were no ill effects, except a slight rise in temperature, from manganese given intravenously in doses of two c.c. twice a week for a total of ten to twenty injections. If improvement took place, it usually appeared after the eighth intravenous injection. If no improvement was noticed after twenty injections, treatment was discontinued. The final results were observed in thirty-one patients. Twenty-one of these received intravenous and ten, intramuscular injections. Eight patients (seven with intravenous and one with intramuscular injections) were cured, seven (four with intravenous and three with intramuscular injections) showed paling in the centers of the lesions, but no other change, six patients (five with intravenous and one with intramuscular injections) obtained no benefit. One patient was cured after one intravenous injection which caused such a severe reaction that the treatment was discontinued. In all of these patients, a five to ten per cent ammoniated mercury, or sulphur, salve was used locally. Nine (five with intramuscular, and four with intravenous injections, combined with the use of a cignolin or chrysarobin salve) had no better results than with the salve alone. Only one patient, who received intramuscular injections, showed essential shortening of the usual time required for the disappearance of the lesions with chrysarobin. In no patient was the appearance of recurrences delayed by the injections. Bohnstedt concluded that the results were not favorable.

Richter^{2c} reviewed the literature on the results of the treatment of psoriasis with manganese, and the experimental work and theories leading to its use in this condition. He thought that the superior results obtained by himself and others with intramuscular, compared with intravenous, injections might be due to a slow, continuous absorption from the intramuscular deposit, and that the different healing effects might be caused by the difference in surface tension of the coarse and fine forms of the colloid. In a series of cases, he confirmed the reports of other workers who obtained more favorable re-

sults with the combination of a new intramuscular preparation with intravenous injections. He stressed the fact that, as with arsenic, one must find the ideal dose for each individual patient. He concluded that manganese was a worth-while treatment of psoriasis and that it was good alone, but much shorter courses were required when it was combined with ordinary methods, and that milder local preparations could be used effectively in conjunction with it.

Fruend and Ravalico⁸ treated eighteen patients with intramuscular injections of manganese dioxide. Eleven were healed, three improved, and four remained unchanged. They obtained better and quicker response when the injections were combined with local therapy. The manganese so increased the sensitivity of the skin that good results followed the use of weak salves which were ordinarily ineffective. They used 0.2-0.5 per cent chrysarobin ointment or zinc oxide ointment containing ten per cent tar, and, in some severe cases, Sabourand's pyrogallol combined with arsenic internally.

Geyer and Wesener⁹ stated that the severe local pain from intramuscular injections of manganese, reported by earlier authors, had been greatly lessened by the addition of a local anesthetic, percan, but that high fever, eruptions, and visual disturbances continued to occur. As they had found that improvement in psoriasis usually appeared after three weeks with other methods, they observed their patients at this time. Of eighteen who received intramuscular injections, under three weeks, three were improved and two no better, over three weeks, eight were no better, four improved, in one, the result was unknown. They also treated eight patients intravenously. Five showed no improvement over three weeks, under three weeks one was improved and in two the result was not known. They gave an average of ten injections with a total of fifteen c.c. The injections were given every two days, the dose varying from 0.25 to two c.c. Salves (cignolin and ochrosilpaste) were also used. The reactions and fever were less severe with the intramuscular injections but these were all painful. They found no changes in the blood, or any renal damage. In some forms of psoriasis, there appeared to be

an acceleration in the healing. In general, however, this was no more rapid and there was no longer period of freedom from lesions than with other methods. They obtained somewhat better results with intramuscular, than with intravenous, injections. They considered the latter a complete failure. Their final conclusion was that manganese showed no advantages over other methods used in the treatment of psoriasis.

The two latest reports on the use of manganese in psoriasis come from this country, and are the only ones in the English language since the original article of Moore. They are both very enthusiastic over the results obtained with this method. Bowden¹⁰ gave injections of colloidal manganese to thirty-four patients with various types of psoriasis, for which they had received a large amount of previous treatment. The injections were given at first once, and later, twice a week. At first, one cc was given intravenously, later, two cc. The initial intramuscular dose of one-half cc was gradually increased to two cc. Sixteen to twenty-four, and occasionally thirty, intramuscular injections were given in two to three months. The majority of the patients showed decided improvement after the second or third injection. Several were completely well after only eight alternate intravenous and intramuscular injections. There were no reactions except fever from 102-104° F and occasionally slight headaches, and no evidence of metallic poisoning nor albuminuria. Twenty-seven of the thirty-four patients were completely cured, and the remaining seven were greatly improved. Three, who were not cured when the injections were stopped, were well after two months.

Barr¹¹ reported in detail on seven patients with psoriasis, treated with intravenous injections of a preparation containing twenty-nine mg of manganese chloride and 9.5 mg of calcium chloride in five c.c. of a physiological solution of sodium chloride. Five of these showed complete improvement and two partial improvement, without any local therapy. Three patients remained free from eruption for over a year after the injections were discontinued, the others had not returned for observation, or were still under treatment. There were no severe

reactions. He has used this preparation successfully for two years, and has given over one hundred intravenous injections with no reactions except a slight increase in the pulse rate, mild suffusion of the face, and a slight feeling of light-headedness, all of which lasted only a few seconds. These were no more marked than the reactions occurring after the intravenous injection of any colloid. In some patients who improved slowly, more marked improvement was obtained by decreasing the dose and increasing the intervals between treatments. None of his patients received any local therapy. Of ninety-five cases, sixty-eight per cent showed total improvement, twenty-one per cent partial, and 9.5 per cent no improvement. He concludes:

Its freedom from toxicity, the ease of administration, the rapidity of the disappearance of the lesions without any local therapy, places manganese chloride at the head of the list of preparations used in the treatment of psoriasis.

Results

From October 1933 to the present date (April 1936), seventy-two patients with psoriasis have been given weekly intramuscular injections of one cc of colloidal manganese. None received any additional treatment such as diet, internal medication or radiation,* and only sixteen, any active topical remedies. It was intended to give only a placebo ointment to all the patients but either through misunderstanding of this purpose on the part of some other member of the staff or through the insistence of the patient on a more rapid result, this was not possible in these sixteen patients. Although even an apparently inert ointment may have had some therapeutic effect, in order to obtain the patients' cooperation it was necessary to give some topical remedy. All but five in this series were seen at the New York

*Two patients were given the injections during a course of x-ray therapy. They have been included in the group of those who improved because in one, the usual recurrence after radiation was delayed several months and was much milder than ever before, in the other, the amount of radiation required to effect a complete disappearance of the lesions was definitely decreased.

Post-Graduate Hospital Dermatological Clinic or at the Skin and Cancer Unit of the New York Post Graduate Medical School and Hospital. There were thirty-eight men and thirty-four women. Most of these patients had severe generalized psoriasis of many years' duration and had received much and varied treatment with only temporary or no improvement. These seventy-two patients received a total of 696 injections with an average of 9.68 injections per patient. Thirty-four improved (disappearance or fading of some of lesions), thirty-three showed no improvement, and in five the result was not determined. Those who improved received 382 injections with an average of 11.24 per patient, those who showed no improvement, 296 injections with an average of 9.0, and those in whom the result was not determined, eighteen with an average of 3.6. The small average number of injections in the last group is due to the fact that these patients left the clinic before the result could be determined and have not responded to requests to return for observation or they have only recently started the treatment. The difference between the average number of injections received by the patients who improved and those who showed no improvement is largely due to the fact that several of those of the latter group who failed to improve at first became discouraged and refused to continue the treatment. In the group of thirty-four patients who were regarded as improved, only two (in one the eruption was limited to a palm-sized patch on each knee) were completely cured and one who was entirely well had a recurrence three months later. Eight others who showed considerable, but not complete, improvement also had a recurrence. The remaining twenty-three showed varying degrees of improvement but were far from completely cured. Six of these are still under treatment. Eight of the patients in whom the final result was unsatisfactory showed some improvement at first but this did not continue or there was a recurrence. In one patient, the scaling was controlled by a salve containing ten per cent ammoniated mercury and five per cent salicylic acid and in another by boric acid ointment, but in both, when the salve was stopped, the scaling recurred even during

the injections. Of the total number of seventy-two patients, fifty-two received no topical remedy except boric acid ointment, eleven used an active salve (chrysarobin, or ammoniated mercury alone or with salicylic acid in various strengths), five an active salve during part of the time and boric acid ointment during the remainder, and four no external applications of any kind. Twenty-four of the first group, two of the second, and four in each of the last two groups were improved. It can be seen that, in this series, the injections did not reinforce the effect of active topical remedies as the results were worst in the group of patients who were inadvertently given these in addition to the injections. This is contrary to the findings of several of the authors previously quoted who reported the best results from the combined treatment. Four patients received manganese butyrate instead of the colloidal form. Two were no better (one even with the addition of chrysarobin ointment), one improved without any salve, and one improved while using an active salve during the injections but the eruption recurred.

Several interesting phenomena, some of which have not been mentioned in other reports, were observed during this treatment. For some unexplained reason, in almost all of the patients the lesions on the trunk responded better than those on the extremities, and those on the face and scalp were most resistant. In a few patients, the lesions on the trunk and extremities had practically, or entirely disappeared, while those on the face and scalp remained unchanged. This required the use of active topical applications on these areas to obtain the patients' consent to continue the injections. In some, as one intelligent patient expressed it himself, the eruption appeared to be "driven" from the trunk to the extremities. Another finding which is difficult to explain, was that in a few patients new lesions appeared during the injections even while the old ones were fading. In others, although no new lesions appeared the old ones became worse while still under treatment. In most patients who improved, as has been frequently previously reported, the patches first cleared in the centers and the edges were much more resistant to treatment and in several

cases never completely disappeared. Two patients in this series had a linear type of psoriasis limited to one side. One of these failed entirely to respond to treatment, the other showed only slight improvement at the beginning but no further progress after a total of ten injections. In three patients who stopped the injections before

turbance. One patient had edema of the ankles for three weeks, after only one injection. In one, a mild, itchy, red, papular dermatitis of the face and neck, the cause of which could not be determined, appeared following the fourteenth injection. This disappeared in one week and the injections were continued without

TABLE I
RESULTS OF VARIOUS AUTHORS WITH COLLOIDAL MANGANESE IN TREATMENT OF PSORIASIS

Author	No of pts	Drug	Dosage	No of admin- strations	Mode of therapy	Local therapy	Reactions	Results	Conclusion
Moore	37	Colloidal manganese	1 c.c.	6-16	Intrm weekly	None	None mentioned	All cured	Favorable
Richter	26	Colloidal manganese	1-4 c.c.	10-16	Intrm. twice a week	None	Slight fever and local pain	Excellent in 20	Very favorable
Schmidt	11	Psoriman-gan	1-4 c.c.	15-20	Intrm. twice a week	Chrysa-robin	Very severe	No cures with injs alone	Very unfavorable
Abramson	20	Psoriman-gan	1-3 c.c.		Twice a wk. mostly intrm.	1% cignolin vaseline	No severe	100% cures with combined treatment	Very favorable
Szego and Von Luka	27	Psoriman-gan	1-2 c.c.	12-16	Intrm. once or twice a week	Yes	None	16 completely cured 8 partly 3 not improved	Very favorable
Bohnstedt	21	Psoriman-gan	2 c.c.	10-20	21 intrv 10 intrm. twice a week	Yes various types	Very slight from intrv	9 cured (8 intrv & 1 intrm) 7 imprv'd (4 intrv & 3 intrm) 6 not imprv'd 9 (4 intrv & 5 intrm.) with chrysa-robin salve no better than with salve alone 11 healed 3 imprv'd 4 unchanged	Unfavorable
Freund and Ravalico Geyer and Weisner	18	Psoriman-gan			Intrm.	Yes			Favorable
	26	Psoriman-gan	0.25-2 c.c.	Average 10	18 intrv 8 intrv every two days	Cignolin & ochrosil-paste	Yes	Intrm 7 imprv'd 1 (?) 10 no improvement. Intrv 1 imprv'd 2 (?) 5 not imprv'd 27 entirely well 7 greatly improved	Unfavorable
Bowden	34	Colloidal manganese	1-2 c.c.	16-30	Intrv & Intrm. once to twice a week	None	Slight fever headache		Very favorable
Barr	95	Manganese chloride	29 mg		Intrv		No severe	68% total improvement 21% partial improvement 9 3/4% no improvement 34 imprv'd 33 no improvement, 5 result unknown	Very favorable
Niles	72	Colloidal manganese	1 c.c.	Average 9.68	Intrm weekly	None	Nil		Unfavorable

complete cure, improvement continued with no other treatment except the use of boric acid ointment. In one patient, the complete disappearance of the eruption under treatment was followed by leukoderma psoriaticum at the sites of all former lesions.

As a rule, the treatment was well-tolerated except for occasional slight local pain at the site of the injection. There were no severe reactions of any kind. In one patient, the injections were followed by anorexia and insomnia and in two, they were stopped because of gastric dis-

any ill effect. Another patient had a generalized, itchy, fine papular eruption after the fifth injection. She stopped treatment because of the itching and an aggravation of her psoriasis. One patient had a severe loss of hair after four injections. This gradually ceased after stopping treatment.

Comment

As was mentioned in the review of the literature, because of its stimulating effect on oxidation in the epithelial cells, theo-

retically, manganese should be of value in the treatment of psoriasis but, unfortunately, this did not prove to be the case in this series of patients. On account of the apparent logic of manganese therapy and the inadequacy of our present treatment of this disease, I started this work in October 1933. At this time, there were several very favorable, as well as unfavorable, reports in the German literature but none in the American. Although my results were more satisfactory than those of some of the authors quoted, they were not nearly as good as those of several others and fell far short of the glowing reports of the manufacturers of the drug. It is difficult to reconcile the contradictory reports of several authors using the same drug in approximately the same manner. My poor results may have been due to the use of only intramuscular, and no intravenous injections, too small doses, weekly, instead of bi-weekly, treatments, and, in most patients, the application of only a placebo salve. I considered that intravenous injections were too dangerous, that weekly intramuscular injections should be sufficient, and that the individual dose should not exceed one c.c. I did not prescribe active topical applications in order not to obscure the effect of the treatment. In those patients, however, to

whom strong salves were inadvertently given, improvement, as a rule, was no more frequent or rapid than in the others or with the salve alone. The number of injections, ranging from four to twenty-seven, appeared to have no influence on the final outcome. Most of the patients who received the largest number of injections showed no benefit and the three who were entirely cured had only eight, six, and nine injections respectively.

Conclusion

While the results are, occasionally, temporarily good, this treatment is too long, uncertain, and potentially dangerous to be considered a valuable aid in the treatment of psoriasis. Only two or three patients were completely cured and so relatively few were definitely benefited that these results may have been due to the softening effect of even the boric acid salve or to a spontaneous remission, as occasionally occurs in this disease. The injections did not appear to prevent recurrences nor delay their appearance, in fact as mentioned above, in some patients new lesions appeared even during treatment. Local therapy was not more effective or rapid during or after the injections than before.

Discussion

DR. FRANK C. COMBES, New York City.—It is refreshing to hear a piece of therapeutic research so ably presented. Dr. Niles is to be congratulated for his honest and unbiased report on the therapy of this intractable disease. Robert Willan, in 1809, first described psoriasis as such and differentiated it from other dermatoses. It was not until 1876 that chrysarobin was used in the treatment. The discovery of its efficacy was entirely by accident, as the preparation had been previously used and with success in fungus infections. It is still probably the most effective remedy at our disposal.

The empiric nature of chrysarobin and its limitations have for years been appreciated. As a result many other methods of therapy have been advocated. Many investigators in their enthusiasm have allowed the personal equation to influence the accuracy of their reports. Manufacturers have frequently and unknowingly advocated the use of preparations for the treatment of the disease which have been worthless. Editors of scientific journals deserve our sympathy in their efforts to eliminate quasi-scientific papers based on insufficient and improperly controlled investigations.

It is unnecessary for me to mention the many methods of therapy advocated for the treatment of psoriasis. Manganese is one of the more recent. It is an occasional constituent of organic tissue and has been detected in minute quantity in various parts of the human body. It is probably not a normal constituent of any human tissue, although some physiologists claim that it exists in small quantity in the blood and bile in connection with iron. If psoriasis is an infectious process it is conceivable that manganese may in occasional cases be effective. It has proven so in some cases of staphylococci. If it be a deficiency disease or evidence of metabolic disturbance I cannot understand how small quantities of this metal can be corrective.

DR. HERMAN GOODMAN, *New York City*—Some ten or eleven years ago, I reported on the colloidal manganese in psoriasis and although at that time I had seen favorable results in a number of cases, I must confess that the patients who had psoriasis then have evidenced psoriasis since.

For many years, however, I believed that one of the patients had no recurrence. In fact, she married under the impression that having been free of psoriasis for a number of years, she would continue with a normal skin. She returned with a psoriatic eruption as do practically all the patients who have true psoriasis.

My conjecture as to the mode of action of colloidal manganese in psoriasis was that it affected the enlarged capillary blood vessels within the derma.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B. LIBER, M.D., DR. P.H., *New York City*

Editorial Note: Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine.

A Mother's Son

It frequently happens that a strong attachment to a patient's mother interferes with his falling in love with any girl. Even the ordinary public is aware of such occurrences, which are expressed in the popular anecdote of the young man who, when reminded by his father that he must get married, said he was ashamed to do so and at the father's objection that he himself had done the very same thing, the boy answered that it had been easy, of course, to marry mother instead of some stranger.

But this exaggerated affection for the mother or father is not always apparent and sometimes it is so hidden that it is quite difficult to discover, especially in people who have read modern books on psychology and know what questions to expect from a mental hygienist.

One man over thirty who had never married, but had had many sweethearts, was forever unsatisfied and unhappy. Always complaining of impotence, he never discontinued to seek a cure, for which none of the ordinary treatments could help him. He said he will not marry unless he is sexually perfect. On the other hand his ideal was, as he claimed, married life.

That the cause of his impotence was neither organic nor neurological became evident during one of his talks when he was caught unawares.

He said

"The woman with whom I have relations—or try to have—is to me like a mother. Her bare body receives me in friendship, gives me shelter, protection, safety, comfort. I feel like a suckling baby asleep with the mother's nipple in his mouth. I am a young kitten lying between the widely outstretched paws of the big cat. A fetus who is re-entering the parts from which it has emerged. Each time I lived with a woman I experienced the same thing."

That was the key to his psychology.

Then came all sorts of confirmatory slips of the tongue, like "Some people want to accumulate *mothers*, I mean money," which further exposed his mental trend.

From then on it was easy. His childhood and adolescence unfolded themselves in quick succession. A flood of light was shed over his entire life and helped him to throw off the inhibition that made him both impotent and unable to unite with any woman and which marred his happiness with deep melancholy bordering on mental illness.

He was told that he could not expect to be perfect at the intercourse, that this was not an absolute necessity for his well-being and that a woman who would care for him could become adjusted to his needs. Instead of waiting for his impotence to be

cured in order to marry, it was more reasonable to believe, in his case, that married life would cure his impotence.

This was precisely what happened. As soon as his impotence ceased to be an obsession, a problem, as soon as he was not so tense about its solution and as he relaxed in the performance of the sexual act, he

had both a normal libido and better erections. It is the same with the stutterer who cannot speak because he tries too hard, and with other similar functions.

This was at the same time a cure for his mental condition and a discipline which he sorely needed in his irregular life.

Poor Pat

Pat is a sixty-four year old man who immigrated from Ireland in his teens but still rolls his *r*-s heavily and uses expressions from the old country. As he sits down near my desk in the clinic I feel a shock. He looks exactly, except for his clothes, like Brueghel the Elder's "Shepherd." Indeed he is and feels just as timid and downtrodden as his brother of the sixteenth century painted with so much love and sympathy by the Flemish artist. Mentally he resembles also The Man With the Hoe or, still better, Anatole France's Crainquebille who has been functioning in this world all his life but who does not understand it and who is finally crushed by its intricacy and magnificence.

"I am affeared," he says and he cannot continue.

With much coaxing I succeed in understanding him.

Pat has been working as a laborer everywhere and for everybody. He has helped building bridges and tunnels, breaking rocks for foundations, clearing fields, blasting roots, loading and unloading coal, making and mending roads, tending furnaces, cutting wood. He has been in blinding dust, in suffocating and poisonous vapors, in dry deserts or half immersed in freezing water. Many times injured and often almost killed in accidents.

He was never afraid until lately. He never worried.

In the first place he finds no work. Nobody wants him. His future, yea, his immediate future is dark. He sees nothing ahead of him. He does not consider applying for public relief, because it is a nuisance to him who has never gotten anything for nothing and because he still hopes to find a job.

Only now he looks around himself and feels the pangs of isolation. He was never married. Why? The answer is, he could never afford it and no girl wanted him, which means that no one went out of her way for him, and he was too shy to approach any woman. He has no family ties in America and he has forgotten those he

had abroad. He used to drink with some friends, but now they don't care for him. He is unable to pay either for them or even for his own share. When they see him they look away.

He is unhappy "the worst way," being somewhere between two situations. To be on the brink of uselessness is what offends him mostly. He may have to become reconciled with the idea of dependency, but he is still resisting and is yet in a faint state of inner rebellion, which is getting feebler every day.

And he is devoured by a feeling of terrific sinfulness. In his day he often drank. He earned enough, didn't he? he explains. And worse than that, he masturbated. Of course, he does not use this word and acknowledges his transgression only after deep probing. Not now! He protests as quickly as his general sluggishness permits him.

And as he feels a greater nearness to his Maker he goes more often to Church, where he confesses those two sins. But, to his amazement, confession brings no solace. Perhaps because nothing worth while is said to him. There friendship eludes him.

So he turns to the doctors.

His eyes are humid because, humble as he is, this is a worse humiliation for him.

Well, his arteries are older than his years. And he is mentally *senile*. Not dull, although in his present misfortune he may appear so. He is really of average intelligence—average for his social status.

While it is impossible to give him back a young mind or a fresh body, and to restore the elasticity of his blood vessels, something is accomplished by encouragement, by assuring him that his sins are not bad or harmful since they have not harmed him so far, and by getting him used to the possibility of receiving relief, indeed by sending him to the proper place for that purpose.

He kisses the doctor's hand before the latter could be withdrawn, he picks up his cap which he had reverently placed on the floor, and he departs.

Several such heart-to-heart talks were necessary in this case.

The Federal Reorganization—A Medical Department

The various suggestions put forward in Washington for the reorganization of governmental and departmental bureaus must impress the philosophic observer with certain pertinent facts. Cross currents of pressure groups, acting in self-perpetuating interest press their claims for consideration in opposition to those who desire to see the reorganization take the line of increased efficiency and perhaps also of economy. Those in power are now learning what we have so often stressed when warning our people and its elected representatives against measures aimed at delivering medical care to our people by any scheme which necessarily would embrace the establishment of another great bureaucracy.

If one examines the situation present in Washington today, one cannot but be impressed with the growth which has taken place of a formula of government hardly contemplated by the founders of our nation when they divided our government into its three fundamental branches, the legislative, the executive, and the judiciary. Many thoughtful observers for a long time have looked with deep concern upon the growing evidence that much government activity was carried on by "Commissions" and by "Committee agencies," in which the division of authority

into the three aforesaid governmental functions were sometimes combined, and often confused. The party in power can do the people no greater service than to keep in mind the possibility of returning our government to the three fundamental channels, with their inherent checks and balances, so that its parliamentary framework may live and properly function. For our form of democracy has been found good for our people, and has stood the strain under conditions of development, in eras of prosperity and in those of depression, in eras of war and of peace.

Our particular interest now, in this contemplated reorganization is deep, not only as citizens of a great democracy, but as a group interested in delivering a vital service to the public. We may be pardoned for claiming, in view of our past and present service to the public, that very important considerations of public welfare prompt our suggestion that serious consideration be given *now, to the establishment of a federal department in which all activities having to do with the promotion of health and the prevention of disease might with evident advantage, be combined*.

Welfare work and its regulation and supervision must not be confused with the maintenance of health, and the pre-

vention of disease. Welfare work has a distinct field of its own. Leaders in welfare work—sociology—are not by training, experience or attitude fitted to supervise, regulate or make recommendations regarding medical problems. The chaos resulting from the ill-considered ideas of sociologists to impose on the country a system for delivering a lower grade medical service based on the foreign insurance conception, rather than evolve an American plan which would maintain American standards of living, wages and medical care, is but a case in point. Too often these sociologists lack the necessary technical training in our vital traditions, and they recklessly, ignorantly, or blandly and innocently send to the scrap heap traditions and even principles which are integral fundamentals in medicine.

The questions concerned involve hygiene and occupational hazards in the home, school, factory, farm, and mine. The nation needs regulatory advice, and supervision regarding health standards, and preventive and prophylactic instruction from its prenatal stage through its lifespan to old age. The rehabilitation and re-education and the conversion into useful, productive members of society of the physically and the mentally handicapped is the concern of a medical group, not a welfare-group, and even crime prevention to many of us presents a medical rather than a law question.

The health of its people is the prime concern of the State. A governmental department should be set up to combine all the nation's medical activities, *and the head of this department should be a doctor of medicine*, with high administrative and executive abilities.

An Illuminating Contrast

Medical Expense Indemnity Insurance, introduced by the Non-Profit Mutual Benefit Association of Brattleboro, Vt. thirteen years ago and adopted with slight modification by the Spaulding (Bakeries) Employees Benefit Associa-

tion around 1930, furnishes some interesting comparison with compulsory health insurance. In their entire approach to the problem of medical care, the difference between the two plans stands revealed. The former helps the low income classes *to help themselves* to provide adequate medical service adapted to individual needs. The latter forces the worker to subscribe to one of those uniform systems that Mr. Richard M. Bradley likens to a universal garment—"* * * seldom a fit for any particular individual."

Repeated surveys have shown that only the protracted illness or lesion requiring major surgical intervention disrupts economic security. The great majority of people are able to pay for the necessary occasional visits of the family doctor out of current income or savings. It is sheer waste to spend the taxpayers' money—and that means the money of all of us—on an elaborate bureaucratic system for this purpose. By eliminating coverage on trivial illnesses that are no serious problem to the worker, the costs of medical indemnity are reduced, operation is simplified, and the opportunities for petty malingering are removed.

A large insurance company, after studying a typical year's expenses for the 37,000 persons comprising the families of its employees, found that "about 4 per cent of family income provides the average American family with all needed care including hospital, nurse and dentist. The Brattleboro and Spaulding plans require less than 1.5 per cent of family income to provide for major illness, leaving a margin of 2.5 per cent for other medical expenses. By the most conservative estimates, compulsory health insurance would cost 7 per cent.

Under non-profit medical expense indemnity insurance, the high standards of independent private practice are encouraged "the worker pays for what he wants, and gets what he paid for." Under compulsory health insurance, there is neither time nor incentive for thorough investigation of cases. A hasty diagnosis and a bottle of medicine are the rule. "The

worker pays, and takes what he gets, whether he likes it or not." (Quotations throughout are from an illuminating booklet issued by the Committee on Economics of the Medical Society of the State of New York)

Nothing in the experience of European countries justifies the extension of compulsory sickness insurance to the United States. Mortality rates are lower here, the standards of professional service higher, preventive medicine more advanced. For the most part agitation for obligatory prepayment for illness comes from politicians and social welfare workers eager to obtain control over medical practice. It is a primary principle of the Brattleboro and Spaulding plans, in contrast, that the lay insurance organizations must confine its responsibility "to the payment of lay obligations," leaving the control and development of medicine to the physician.

This is *not* an endorsement of the Brattleboro or Spaulding plans in their entirety. They do, however, suggest that there are other methods capable of dealing with the question of medical care for the under privileged more efficiently than compulsory health insurance and without the latter's damaging influence on medical standards and public morale.

At the January meeting of the Executive Committee of the Medical Society of the State of New York, a committee was appointed to make an intensive study of these and any other systems which promise to contribute to the solution of a problem on which decisive professional action must soon be taken.

Why Not Here?

The January ninth issue of the *J.A.M.A.* carried a news item that bears repetition. The national legislature of Argentina has set aside an annual fund of five million pesos (about two and a half million dollars) to pay physicians for their work in the public hospitals. While the rate of payment under this budget will

necessarily be modest, the bill is a great triumph for the practitioners of Buenos Aires who have campaigned for this reform. Moreover, it sets a highly important precedent.

There is every reason why this country should follow the example set by Argentina. The United States does not as a rule fall behind South America in its conceptions of governmental duty. The physicians of New York State are no less conscientious or efficient in their services to the public hospitals than their Argentinian colleagues. Argentina has shown itself generous and just in acknowledging that the sick poor are the responsibility of the entire community, not of any one profession. New York State should not continue to keep its eyes closed to this incontrovertible fact.

Financial considerations furnish no excuse for city and state failure to relieve the medical profession of the burden of the indigent. The government does not take economic stringency as a warrant to saddle other professional or industrial groups with its responsibilities. In spite of gaping budgetary deficits, governmental agencies are busy with schemes to spend taxpayers' money on unnecessary services to wage earners who are well able to provide for themselves. Surely it is their first duty to pay for medical care to the needy and dependent.

The precedent set by Argentina cannot long be ignored. This is something that not only *can* but *should* happen here.

Welcome Among Us Dr. José Arcé

Refreshing alike to body and spirit, like the scent and vision of an oasis greeting the sand-bitten eyes and dry, thirsty throat of the weary desert traveller, are the reactions and emotions aroused by the addresses and the responding talks evoked by the presence among us of very distinguished South Americans led by the Dean of the University of Buenos Aires, Argentine Republic.

The occasion was the dinner tendered

by the New York Chapter of the Pan American Medical Association held in the Metropolitan Club, New York City, on January eleventh. The guest of honor was Dr José Arcé. He was accompanied by a group of surgeons—Doctors Adolfo F Landivar, Antonio Egues, and Isidore Castillo Odena. Dr Arcé's address on "The Future of Pan American Medicine" is published elsewhere in this issue [page 327].

To greet these eminent medical men, the New York Chapter of the Pan American Medical Association assembled a very representative group of medical authorities from many fields of American medicine. Dr Charles Gordon Heyd greeted the visitors for the A M A, and Dr Adolph G DeSanctis, President of the New York County organization, represented the local group in organized medicine. The Executive Committee of the State Society, at its last meeting, nominated Dr José Arcé for honorary membership. At the gathering, the great scientific and educational medical institutions of the vicinity of New York were well-represented, for the development and advancement of graduate education seems to concern these visitors. They envisage the development of great teaching centers, and an exchange of professors and scholars, working under scholarship awards, between the countries of Central and South America and us. They cordially desire that we of North America, shall visit and study them and their institutions of learning.

We should do this. We, in this country, have too long kept our eyes turned toward Europe whence came to these shores—for the most part—our ancestors. Almost subconsciously, we looked for guidance in advances in scientific medicine to the European cultural centers. But Europe, torn by hates, is separated by ideology of governments, and except in the great democracies of England and France, its people are rigidly regimented even in their thinking, and strictly limited in the development of their activity by racial and geo-

graphical lines. Endeavor is made even to confine medicine to national boundaries. Meanwhile, to the south of us, under the impetus of freedom of thought equal and analogous to our own, great free institutions are developing, and fine intellectual achievements are being recorded. There, like here, race, creed, and nationality are subservient to intellectual integrity and honesty. There it is also held true, as it is in democratic England and France and here, that science—particularly medical science—knows no boundaries and is not considered an inherent gift of any one people, race or geographical unit.

Dr James Ewing remarks on the crucial period through which the world is moving, and wisely calls to our mind the truism that man is best judged by his philosophy of life. Likewise nations are less to be esteemed and estimated by their accumulations of grim armaments, or even art treasures denoting past glories than that the standards of their state of civilization must be ascertained by the philosophy of living which the people of a government exhibit and preach. Study of the underlying philosophy of most European governments and people leaves us almost in despair, and we sense that the very future welfare of mankind is more dependent than most of us realize upon the maintenance on this Western hemisphere of a philosophy of living which encompasses freedom, not only of political thought for all peaceful activity, but especially intellectual freedom for scientific advancement and achievement.

We welcome Dr José Arcé and his distinguished colleagues! The ever recurring interchange of ideas and visit among North, Central, and South Americans only can result in better mutual comprehension and appreciation. Perhaps in the not too distant future, Europe will recover from its present mental madness, recapture its poise, and cease bending all its efforts to mold its peoples for war and devastation. Then, perhaps taking example from the Americas where

the torch of liberalism burns brightly and readily, Europe too will join us in developing constructive ideas for the betterment of mankind

Pneumatology!

The use of various gases in therapeutics has increased tremendously during the past ten years. Limited as once they were to the field of anesthesia, many of them have been found efficient in the treatment of asphyxia neonatorum, carbon monoxide poisoning, submersion, hypoxemia, and terminal poliomyelitis. The practical employment of the gases is scattered among various branches of our profession and embraces also the rescue squads of the Police and Fire Departments. Occasionally, the anesthetist is called upon

But it is the latter, contends the "Society for the Prevention of Asphyxial Death," and rightly so, who, by virtue of training and ability, is most capable of administering these gases. Only the lack of a generic term adequately to describe the collective uses of "gas therapy" seems until now to have frustrated the expansion of the *anesthetist* into a *gas-therapist*! The term *Pneumatology* is suggested as best describing the science of elastic fluids or pneumatics. And so our *anesthetists* are to be metamorphosed into *pneumatologists*. Ah, but here's the rub!

Derived from the Greek, *pneumatology* is properly defined¹ as "the science of the nature and operation of spirit, or a treatise on that science, the science of spiritual existence, formerly divided into (1) *theology*, treating of God, (2) *angelology* and *demonology*, treating respectively of angels and demons, and (3) *pneumatology proper* (now *psychology*), treating of the human spirit."

It also indicates "the science of the beliefs of men touching a world of spirits." In theology it concerns itself with the "doctrine of the Holy Spirit."

Verily, our brethren in the gaseous fields of Aesculapius would betake unto themselves many and divers enterprises mostly alien to our noble calling. Another very eminent specialist engaged in this work has suggested the term "Anesthesiology."

While we pause, awaiting the final action of the neologists, we sympathize with the efforts of the Society for the Prevention of Asphyxial Death, and offer counsel to the end that they continue their search for a more suitably descriptive name—one that will represent a happy union of the gases without the terror of demons and spirits, aye, even of angels, hovering close at hand!

The Doctor and Traffic

Despite the mechanical perfection which the modern automobile possesses, motor car accidents are occurring with increasing frequency. As a result, the ingenuity of the surgeon has been taxed to devise new technics for the treatment of new types of fractures and other forms of trauma which have made their appearance since the increased use of the automobile.

It rapidly is becoming evident to all concerned in the study of traffic problems that the human element is as important a factor in the production of motor car accidents as is the mechanical condition of the vehicle itself. There is a concentrated campaign now in progress through the radio, and in the press for a more stringent attitude in the granting of drivers' licenses. A plea is made for the elimination of those having physical defects which would in any way render the applicant unsafe at the wheel of a car.

The testing at the present time is in the hands of lay employees of the Motor Vehicle Department. Eyesight is tested in the crudest manner possible. The general physical condition is overlooked entirely. The mental status of the pros-

¹ New Standard Dictionary of the English Language, Funk & Wagnalls, New York and London, 1927

pective operator is not taken into consideration. Selling¹ has written a splendid summary of these problems in which he sets forth the duties which the medical profession must assume in coping with the prevention of traffic accidents. Since we are called upon to treat the injured, it becomes our duty to help in reducing to a minimum those hurt as a result of discernable physical and mental defects on the part of the driver.

No life insurance company accepts an applicant without a thorough physical examination. The State, as the protector of the lives of its citizens, should do likewise before putting a potential instrument of death in the hands of anybody. And, it is the family doctor, not the official physician attached to a Commission, who would *know* the epileptic, the feeble-minded, the insane, and the chronic alcoholic—important factors not evident during the examination for the detection of physical defects. In his hands should be placed this phase of the traffic problem and legislation to that effect is urgently needed.

Interesting Statistics

According to the authoritative League of Insurance Physicians of Germany, there were 30,559 insurance physicians employed in the Third Reich in a report under date of July 1, 1936. In 1933 there had been 32,620 physicians so employed. Thus there was a decrease of 2,061 doctors despite the fact that in the same period the number insured was increased by about two million persons. According to the National Bureau of Statistics, the administrative personnel of the sick insurance societies numbered 35,635 persons in 1934, and 36,229 persons in 1935. With an increase in the total number of insured of nearly a million, since 1924 the lay personnel seems to have been increased about 10,000, *but the physicians to handle this larger number were re-*

duced by about two thousand! (Italics ours.)

This bears out our contention, repeatedly made, that for almost every doctor employed in compulsory health insurance, one or more laymen are employed. The Berlin letter¹ in our *J.A.M.A.* throws interesting light on this and other questions. It should be studied by us all.

CURRENT COMMENT

"THE INVESTIGATOR WHO SEEKS to expose the fallacy of any long-established dogma and who thereby disturbs the serenity and ease of less ambitious mortals is certain to arouse antagonism and excite hostile criticism rather than to evoke a eulogium upon his efforts, and should he persist in his reprehensible course of shattering cherished ideals he comes to be regarded as a meddlesome fellow and a discordant element in his professional community."—Back in 1905 Dr. Frederick Whiting came to this conclusion and stated it in his book *The Modern Medical Operation*, and we quote it here because it seems to be one of those eternal verities, always applicable to the current scene.

"IN THE PAST TEN YEARS there has been an alarming drop in civil liberties all over the world. Rights painfully won over hundreds of years of struggle are gradually being relinquished by the people or wrested from their hands. A parallel situation exists in the field of healing, where powerful lay forces are attempting to subordinate the medical profession to their interests and control. A great impetus for the destruction of medical independence comes from politicians and professional welfare workers who see in this field a virgin opportunity for the bureaucratic expansion on which they thrive.***

"Under compulsory health insurance the physician would cease to control his own practice and become a cog in a bureaucratic machine, subject to the opinions and orders of his administrative superiors. Voluntary professional union makes for strength. Enforced organization under external control would destroy professional independence and leave the doctor vulnerable to every hint of pressure from above. If physicians attach any value to the untrammelled judgment

¹ Selling, L. S. *The Physician and The Traffic Problem*, *J.A.M.A.* 108 93, 1937

¹ Berlin Letter, *J.A.M.A.* 108 218, 1937

and high prestige they have enjoyed throughout centuries of professional freedom, they will fight insurance schemes in every possible way"—This time the warning, the plea for the maintenance of "independence" for the medical profession comes from the *San Francisco Medical Bulletin*

"IN 1935 THE 4,257 GENERAL HOSPITALS in the United States gave 95,372,310 days of treatment to 6,867,870 patients admitted"—From the *New York Sun* of January 11, and vouched for by the *Annals of the American Academy of Political and Social Science*

"COMPULSORY HEALTH INSURANCE, when it combines insured medical service with cash benefits for illness is not really *health* insurance at all, it is a *tax upon health*, the proceeds of which are used to insure—or rather to *reward*—sickness!*** It is fundamentally different from such judicious forms of 'social security' legislation as old age insurance and unemployment insurance. First, health insurance—unlike old age and unemployment insurance—attempts to insure against a risk that can be, and quite commonly is, *self-induced*. Secondly, health insurance—unlike these other two insurances, involves compulsion upon and eventually the degradation of, a whole profession—a profession the *quality* of whose public service cannot fail to be profoundly affected, almost certainly for the worse, by such a radical change in its economic and social foundations as compulsory health insurance would cause.

"The people of the United States—if they knew the facts, if they understood the issues—would never tolerate compulsory health insurance. Who is to tell them the facts? Who, indeed, if not the physicians?"—We agree with the *Westchester Medical Bulletin* of January 1937, from which we have quoted the above, and we feel, as its editors do, that if compulsory health insurance of some sort or other is not to be "put over" on the American people they must be forewarned with facts and they can best be forewarned by their physicians

"THE SAVING OF LIVES IS NOT ENOUGH. The perfecting of lives should be the aim. Medicine must ally itself with those forces which make for the best access to the materials and opportunities which promote happiness and stimulate physical and moral perfection in men and women. Medicine, in the end, must be concerned for cultural

values—the passion for wisdom, beauty, and justice. These are the real expressions of health"—Dr J P Warbasse in his book *The Doctor and the Public*

"THE TENDENCY TO GET BACK to a better appreciation of individual and personal relationships in medicine is quietly gathering strength in a manner which may have deep influence upon the future practice of medicine. It has been discussed under the designation 'Neo-Hippocratism,' which voices a call to go back and sit at the feet of the ancient master. To think of the man as a whole, of his constitution and his nature."—From the address of Dr James Alexander Miller at his inauguration as President of the New York Academy of Medicine at its annual meeting on January 7

At the same meeting Thomas D Thacher, former Federal judge and Solicitor General of the United States, voiced his doubts as to the soundness and validity of schemes of state or socialized medicine. "To put it concretely," he said "figures indicating averages for the whole of the United States are made the basis for the universal application of a single remedy *without* consideration of the *local conditions* under which it is applied. This is a *peculiarly erroneous method of thought and an extraordinarily dangerous method of action*" (Italics ours)

"MUCH HAS BEEN WRITTEN AND SPREAD by means of the printed sheet and by word of mouth about socialized medicine. By far the greatest part of it for lay consumption has been the product of social reformers because medical men have been reticent about publishing their own ideas to the world at large for various and sundry reasons. They have expressed themselves chiefly through the medium of their own scientific journals or at private forums. Much of the little that has been permitted to seep out to the laity has been couched in such exacting language and with such detail that it has been lacking both in appeal and in comprehension to all but a few of those whom it was intended to impress"—*Jackson County Medical Journal*, Kansas City, Mo

"MORE WOMEN THAN MEN ARE studying medicine in Soviet Russia today, according to Dr Henry E. Sigerist, professor of the history of medicine at Johns Hopkins University, who has passed the last two summers studying the extensive development of socialized medicine in the Soviet Union

"In an address before the New School for Social Research *** Dr Sigerist estimated that of the young doctors that will emerge from the Soviet medical schools in the next five years to engage in the ambitious public health program, approximately two out of three would be women

"He attributed this vocational phenomenon to the fact that the demand for engineers in Russia during the last decade absorbed

a large proportion of the young men who otherwise might have turned to the medical profession. Engineers were better paid and accorded more privileges during this period of intensive industrial development, and as a result young women found many opportunities in the medical field ***" From the *New York Herald Tribune* of January 14

To The Editor

I have read with interest Dr Stuart E Krohn's able description of a case of acute recurrent polymyositis associated with blood eosinophilia which appeared in volume 37, number 1, page 10 of your Journal

May I suggest in addition to the differential diagnosis given in the paper, a consideration of the well-recognized and not infrequent association of polymyositis with blood eosinophilia in periarteritis nodosa?

Respectfully yours,

N H SCHWARTZ, MD

January 11, 1937

OUR EDITOR'S "HEART TO HEART" TALK

It reached the point recently where a medical editor in the Southwest felt that he must tell the doctors who were sending in scientific articles for his pages a few things good for their souls. He took his pen in hand and wrote the title, "Our Duty." Then he said, "This is a busy world." Time is precious, life is short. So he comes out flatly without mincing any words, and declares that "the writer who uses an excessive number of words in putting over his message is a robber of his readers' time and a confrere's right to get his message into print. He robs himself also of prestige because his lengthy article has few readers as compared to those his shorter article would have."

It seems that the editor has been doing some plain and fancy cutting, and has perhaps "stirred up the animals," as he says.

It is not unusual for us to delete sufficient words from an article of twelve to fourteen pages to reduce it to six to ten pages with

nothing being omitted except unnecessary words. From other articles we are able to delete relatively few words. Our deletions are in inverse ratio to the care and time an author spends upon his paper. A year or more ago a certain author submitted a paper from which we deleted perhaps twenty-five per cent of his words. This year he submitted another paper and the deletions were negligible. We probably save enough space of each issue to publish perhaps two short papers that would otherwise be crowded out.

In the main our contributors have expressed themselves as appreciative of the vast amount of time we have spent in editing their articles so as to get their ideas across in the fewest possible words. Occasionally an author has said to us in effect, I wish my paper published exactly as I wrote it. Such an author certainly does not understand the problems which confront us.

In confirmation of the editor's contention we have presented his main points in about half the space that he required.

COMMITTEE ON LEGISLATION

January 12, 1937

Although the Legislature endeavored to organize on Wednesday, January 6, the Assembly has not as yet effected an organization. The Senate did organize and has already received for consideration more than one hundred bills. Among these there are several that are of interest to us.

This morning the Senate announced its committee chairmen. A statement of these you will find and notice, please, the two changes in the committees with which we are most closely associated. The Judiciary Committee will be headed this year by Senator Kleinfeld and the Welfare Committee by Senator Livingston.

We shall endeavor to keep you in close touch with what happens in Albany and we hope in turn that you will reciprocate by keeping us informed with the reactions you receive from your legislators when you correspond with them in accordance with our suggestions. You will recall that we have often said that our combined strength depends upon the integrity of the local county unit's relationship. If you and your legislators thoroughly understand each other and are harmoniously cooperating, the medical profession will have nothing to dread.

The following bills have been introduced. Senate Int. 1—Dunnigan, relative to aid to dependent children, child welfare, assistance to blind, Federal aid for child welfare, maternal and child health services and care and treatment of crippled children, and other public health work. Referred to the Relief and Welfare Committee.

Comment This is the social security bill. There is nothing in it that directly refers to the practice of medicine. Nevertheless, it is possible that many would like to read the bill and we shall be glad to send you a copy if you write us a request.

Senate Int. 20—Howard, for regulating private fee-charging employment agencies, and appropriating \$40,000. Referred to the Finance Committee.

Senate Int. 47—Williamson, amending the Workmen's Compensation Law, by requiring commission or board in making award to include therein where claimant is successful, his necessary and reasonable disbursements, and permitting a review by appellate division, on appeal, of both findings of fact and rules of law of board. Referred to the Labor Committee.

Senate Int. 59—Kirkland, amends the

Agriculture and Markets Law, for testing bovine animals for Bangs and other infectious diseases and relative to sale of such infected animals and to indemnities. Referred to the Agriculture Committee.

Senate Int. 67—McNaboe, amends the Public Health Law, for establishing a narcotic control bureau in the Health Department, and appropriating \$25,000. Referred to the Finance Committee.

Bulletin No 2

January 19, 1937

The Speaker of the Assembly announced last night the personnel of the various standing committees and enclosed you will find a list of those with which we are most actively concerned

There will not be much work done by the Legislature this week owing to the fact that many of the legislators have gone to Washington to attend the inauguration of President Roosevelt. This will give added opportunity, however, to those who have not as yet interviewed their legislators to do so, and it also gives an extra opportunity to those chairmen to send us a list of the members of their committees who have not already done so. It is highly important that we should have these names and we hope that if you have not sent us the names of the members of your committee, you will do so at once.

Bills of interest to us are slow in coming in this year. This may indicate that there will be few or that they will be unusually plentiful toward the close of the session. At any rate, bear in mind that every indication is that we shall have another chiropractic bill this year. We are informed that it will contain educational requirements equal to those which are now required of the physicians. Without doubt, the educational requirements will not be applied to those who are practicing in the State now, they will see to it that provision is made for their licensure under a waiver. The bill has not been introduced as yet, but it is not too soon for you to remind your legislators of the value of our single educational standard.

The following bills have been introduced during the past week:

Senate Int 21—Livingston, Assembly Int 188—Hammer, appropriates \$2,880,000 for payment of State's share of cost and administration of aid to dependent children and \$210,000 for assistance to blind, to Social Welfare Department, and \$25,000 to education for administering vocational rehabilitation of physically handicapped under Federal Social Security Act. Referred to the Finance Committee in the Senate and the Ways and Means Committee in the Assembly.

Senate Int 59—Kirkland, Assembly Int 156—Bartholomew, appropriates \$1,000,000 to pay indemnities for bovine animals killed on account of mastitis. Referred to the Finance Committee in the Senate and the Ways and Means Committee in the Assembly.

Assembly Int. 146—Allen, appropriates \$1,000,000 to Agriculture Department to pay indemnities for bovine animals killed on account of Bang's abortion disease, and for administration expenses. Referred to the Ways and Means Committee.

Assembly Int 179—Zimmerman, adds new Article 2-c, Public Health Law, making Health Department the State agency for administering those parts of the Social Security Act relating to maternal and child services, care of crippled children, and other public health work, and defining powers of Commissioner. Referred to the Relief and Welfare Committee.

Assembly Int 179—Zimmerman, adds new Article 2-c, Public Health Law, making Health Department the State agency for administering those parts of the Social Security Act relating to maternal and child services, care of crippled children, and other public health work, and defining powers of Commissioner. Referred to the Relief and Welfare Committee.

LAY ADVICE ON HOW TO HEAD OFF SOCIALIZED MEDICINE

"A storm of criticism" is foreseen as likely to "burst upon Washington" if an attempt is made to force legislation through Congress favorable to health insurance. That is the view of the *New York Herald Tribune*, for, it says, with rare exceptions, every medical association or society, national, state or county, in the United States, continues to be uncompromisingly hostile to "socialized medicine."

Yet it is also true, it adds, that certain conditions exist in this country which argue for a much wider distribution of medical services than now exists, and it argues, as has often been maintained in these pages, that the best way to head off socialized medicine is to remedy these conditions now, before state medicine is called in. It says, in a thoughtful editorial

Most of these conditions and needs are, we believe, recognized by organized medicine. In rough outline they are as follows: There is a big element in the population either needy, ignorant and reckless of health or with low earning power but a real pride that gets much less medical attention than it should. Aside from all humanitarian considerations, this is a matter for grave public concern. Those persons disabled by neglected injuries or illnesses are likely to become permanent and expensive burdens on private charity or public funds. They also incubate sickness to the detriment of the public health. Next, there are more well trained and competent doctors and nurses in the United States than can earn a fair return on their investments in education and training. This makes the cost of medical at-

tention to those of average income, who want medical care and want to pay for it, discouragingly high.

Faced with these conditions, all those persons who would rather have the government take any difficult problem off their minds and solve it expensively and inefficiently than think and work it out for themselves clamor at once for compulsory health insurance under Federal control. Accepting such propaganda as a challenge, the medical organizations become so bitterly (if justly) critical of every compulsory insurance scheme—and are so much on the defensive—that they appear in their publications to be taking a let-well-enough-alone attitude. Against "socialized medicine" in every form that has been tried abroad, they argue from abundant data that it constitutes an enormous tax burden, that it lowers the quality of medical care for all, that it does not improve public health and that it forfeits through perfunctory, impersonal treatment the confidence of those very elements in the population which it is designed to benefit.

These objections, when examined in detail, are enough to line up the average conservative American layman behind the medical profession in its hostility to compulsory insurance. But mere hostility is not enough. The gap in medical care must be studied and a sound remedy devised. Otherwise the "socializer," who has the bit in his teeth, will prevail. To save the medical profession and the nation from the affliction of another European institution, about as well suited to our temper as peacetime conscription, it seems to us that the doctors will have to consider forthwith how medical, nursing and hospital service can be rapidly extended in conformity with the public interest and with their professional ideals.

COMMITTEE ON WORKMEN'S COMPENSATION

January 14, 1937

The attention of all physicians is drawn to Section 13-c of the amended Workmen's Compensation Law

"13-c. Licensing of Compensation Medical Bureaus (1) The commissioner may, upon the recommendation of the medical society of each county or of a board designated by such county society, or of a board as provided in section thirteen-b, authorize and license compensation medical bureaus, operated by qualified physicians wholly or principally for the diagnosis and treatment of industrial injuries or illnesses in respect of which they are authorized to render medical care under this chapter

* * * Application for such authorization shall be made on forms to be furnished by the commissioner and shall disclose in full the nature of the personnel and equipment of such bureaus. No such authorization shall be made in the absence of recommendation from the appropriate society or board. Each such bureau which receives such authorization shall

(a) Make reports on its personnel and equipment in such form and at such times as may be required by the commissioner, and

(b) be subject to inspection by the commissioner or the medical society of the county in which such bureau is located, and

(c) pay to the commissioner a license fee of fifty dollars per annum for each office of such bureau"

Physicians who desire or are required to obtain a compensation medical bureau license are asked to apply at once to Mr

Hugh J Murphy, Compensation Medical Registrar, 80 Centre Street, New York City, for an application blank, which they will fill out, notarize, and return to the Workmen's Compensation Board of the County in which the office requesting license is located.

A physician who practices independently and who is responsible for the treatment of every injured claimant does not need a bureau license. (Where a physician operates one or more offices principally for the treatment of injured claimants under the Workmen's Compensation Act, and employs another physician or physicians upon whom devolve the treatment of injured employees, wholly or in part, must secure a compensation medical bureau license.)

A qualified physician cannot delegate to another physician the treatment of and responsibility for an injured employee and himself render a report and a bill for a case that he has not himself treated. Therefore where a physician devotes himself exclusively or principally to the care of injured workmen, and finds it necessary to employ another physician to assist him and at times to assume part or full legal responsibility for the case, then, in order to avoid the penalty of 13-d-2, it will be necessary for such qualified physician to obtain a bureau license. By so doing he may under section 13-a employ another physician on a salary basis and may himself render a bill without being subject to the penalties of section 13-d.

EDITORIAL YOUNGSTER GETS HIS DUE

One of the most awake and alive medical journals coming to this office is *Northwest Medicine*, of Seattle, and it was with no little interest that an article was found in its December issue telling who is the "guilty party." The magazine has been going thirty-five years and during that entire period the Editor in Chief has been the same man, Dr Clarence A Smith, who first saw daylight in '61, was graduated from Yale fifty-five years back and from the College of Physicians and Surgeons in '87. A few weeks ago some 130 of his fellows gathered at the Rainier Club in Seattle to do him

honor and presented him with a handsome watch as a token of affection and appreciation. It is a pleasure to add our felicitations and best wishes for many more happy and useful years. "He retains," we are assured, "the alert mind, the tireless energy, the keen enjoyment of life which would ordinarily characterize those half his chronological age. His youthful viewpoint, tempered with kindness and sincerity, is a constant source of inspiration to younger members of his staff. His sense of humor makes any work with him a delight. He is truly a happy man."

REPORT OF SUB-COMMITTEE OF THE INDUSTRIAL COUNCIL

July 1, 1935 to December 31, 1936

Report and resume of the work accomplished and the progress made by the Industrial Council and the sub-committee appointed by it in advising the Industrial Commissioner in the administration of Chapters 258 and 930 of the Laws of 1935 amending Section 13 of the Workmen's Compensation Law.

The Industrial Council at a meeting held July 22, 1935, which was attended by the five physician members recently appointed by the Governor as provided by the amendment to Section 13, unanimously adopted a motion that a sub-committee be appointed from its membership to make a detailed study of the medical situation, and to formulate the various poster notices, medical report forms, rules and regulations, etc.

The Industrial Commissioner as Chairman of the Council selected the following members as the personnel of the sub-committee: Dr E C Podvin, Chairman, Dr Wm. Linder, Dr H E Ayers (Alternate to Dr Linder), Mr Thos J Curtis, and Mr Max Meyer.

The Sub-Committee since its appointment in July 1935, has met in session to December 31, 1936, on ninety-six occasions. All members of the Sub-Committee attended all sessions regularly with a very few instances of absences.

The Sub-Committee took under consideration the composition and formation of a poster notice, medical report forms, rules and regulations relating to the administration of the Act and rules for the Industrial Council governing the procedure to be followed in hearing the appeals filed by physicians and medical bureaus.

A poster notice known as form C-105 was completed and perfected which contained instructions to both employer and employees relating to Section 13 which has been supplied to all employers with the direction to post in conspicuous places on their premises.

A medical report known as form C-104 was completed and perfected to be used by attending physicians. A supply of this form has been furnished to all authorized physicians with the direction that this form must be completed and filed on every case treated within forty-eight hours of the first treatment.

The medical report previously used, known as the C-4 form was revised to conform with the amendment to Section 13.

The sub-committee also devoted considerable time and study to the formulation and the wording of various other documents, certificates, and forms necessary to the administration of the Act, and some of these are indicated as follows:

Application blank form to be used by applicants requesting license for the operation of compensation medical bureaus known as form C-100.

A card issued to physicians certifying that they are authorized to do compensation work, known as form C-101.

A certificate issued to all physicians authorized to do compensation work, known as form C-102.

Daily abstract of receipts, used as a record for all monies received by the Department covering licenses issued for medical bureaus and laboratories, known as form C-107.

License certificate for the operation of medical bureaus, known as form C-109.

License certificate for the operation of laboratories, known as form C-110.

Application blank form to be used by applicants requesting license for the operation of physicians' medical bureaus, known as form C-121.

Form to be used by insurance carriers and employers when filing objections to medical bills and requesting arbitration, known as form A-1.

Form of submission to be signed by both the plaintiff and defendant when a medical bill is to be submitted to the Arbitration Committee for consideration and decision, known as form A-2.

As the law permitted employers to recommend authorized physicians to their injured employees when a request was made in writing by the employee, there developed a widespread abuse of this privilege. Various employers were using different type forms to be signed by the employees, and the wording of these forms failed to conform to the letter of the law. It was therefore necessary that the Committee devise a form of waiver embodying the intent of the law.

After careful study of the question a satisfactory waiver form was evolved which is now being used as a uniform standard form by all employers. The following is a sample of the form:

"This form is to be used only upon request of the injured worker after the occurrence of the accident."

193

Employer

Dear Sir —

I hereby state that I do not wish to use my

right to select an authorized physician of my own choice and I hereby request that you select an authorized physician to provide me with the necessary medical care for my injury of (date)

Nothing herein contained shall prevent me from subsequently engaging the services of an authorized physician of my own choice for continuance of any medical treatment or care required

(Signed)

Address

The committee also gave considerable time and study to the compiling of a two page memorandum containing detailed instructions explaining the procedure to be followed by all authorized physicians. A copy of this memorandum has been issued to each authorized physician.

The various forms necessary in the administration of the Act was completed and perfected after numerous conferences held by the sub-committee with representatives of insurance carriers, employers, insurance buyers, state and county medical societies.

Various physicians and groups of physicians objected to signing the application form furnished by the State Medical Society because of the fact that it contained a clause purporting to be a waiver of certain rights of the applicant. It was necessary for the sub-committee to hold several conferences with the physicians in question, which resulted in the physicians agreeing to sign the application without any alteration. The application form, however, has since been altered and modified eliminating the objectionable clause.

The sub-committee was very active in conjunction with representatives of insurance carriers, employers, insurance buyers, and the State Medical Society in establishing a minimum medical fee schedule covering all counties in the metropolitan district. This fee schedule was adopted by the Industrial Commissioner effective May 1, 1936 after numerous conferences held by the Committee, and it was a very tedious and difficult task.

The sub-committee also gave considerable time and consideration to the establishment of a minimum medical fee schedule covering upstate New York, but this schedule has not as yet been adopted by the Industrial Commissioner.

The Committee has devoted much time and study to the problem of a fee schedule covering hospital service on compensation cases. Numerous conferences were held with representatives of hospital associations, state and county medical societies, self-insured employers, insurance buyers, Compensation Rating Board and insurance carriers.

Objection has been raised by both employers and insurance carriers to the adoption of a hospital fee schedule by the Industrial Commissioner on the ground that under the law it is not within the province of the Industrial Commissioner to fix a schedule of fees covering hospital services.

The Industrial Commissioner has requested from the Attorney General an opinion on this point. The Attorney General has not as yet rendered an opinion on this question.

There has been some difference of opinion between the parties as to the proper *per diem* rate chargeable by hospitals, and no agreement has been arrived at.

It was suggested that three certified public accountants be engaged to determine the cost to the various classes of hospitals in the handling of compensation cases. It was agreed that the insurance carriers, insurance buyers, and employers select one, and the hospitals and Industrial Commissioner select one each.

It was then decided to await the outcome of the audit by these accountants before considering the adoption of a hospital fee schedule.

The hospital fee question therefore is still to be decided.

In order to compile proper rules and regulations covering compensation medical bureaus the committee thought it necessary and did visit and inspect several medical bureaus to determine what should be the proper set up, equipment, personnel, and standards requisite for the proper operation of such bureaus.

After an exhaustive study of the situation a set of nine rules were compiled and adopted, which gives a definition of such bureaus, proper location, the necessity for the presence of a physician, how it should be housed, sanitary requirements, necessary equipment, and personnel, etc.

The Committee held numerous conferences with interested parties directly concerned with the administration of the Act for the purpose of setting up and compiling a set of rules and regulations which were needed to clarify many of the specific provisions of the law.

After repeated hearings held for the purpose of considering objections submitted from various sources to the original set of rules, many revisions and corrections were made.

The Committee gave considerable time and very careful study to the editing and the formation of these rules and has now completed this very arduous and trying task, and recommended for adoption a set of twenty-six rules covering the following subjects:

A rule limiting the time for action by a Medical Compensation Board to pass upon physicians' applications.

Rules of procedure to be followed for removal of physicians from panels and revocation of licenses of medical bureaus.

INDUSTRIAL COUNCIL REPORT

321

Rules of procedure for handling appeals filed with the Industrial Council

Rule defining a physician's medical bureau

Rule indicating that all medical reports must be verified

Rule indicating the manner in which, and to whom, medical reports are to be submitted

Rule defining the specific procedures for which physicians must secure authorization from the employer

Rule indicating under what circumstances an x-ray may be taken by other than a physician

Rule indicating the procedure to be followed by physicians when treatment has been transferred.

Rule indicating procedure in case of a serious accident.

Rule governing treatment rendered by a registered physiotherapist

Rule governing the submission of bills by specialists and the securing of authorization

Rule indicating the method of securing hospital records by attending physicians

Rule defining the emergency status of cases public hospitals

Rule indicating procedure of medical inspectors for admittance to hospitals

Rule prohibiting hospitals operating medical bureaus and clinics

Rule indicating license is not necessary to operate a first aid station.

Rule prohibiting advertising on compensation work by physicians, medical bureaus, and laboratories

Rule permitting reduction in size of form C-105

Rule relating to the allowance of fees to attending physicians for appearance at compensation hearings

Rule indicating the manner in which bills are to be submitted covering hospital service, as well as physicians for medical service rendered in hospitals

Rule prohibiting the supplying of names of authorized physicians by insurance carriers to policy holders

Rule governing the procedure to be followed by medical inspectors employed by insurance carriers or employers

Rule governing procedure to be followed when a medical examination is requested by an insurance carrier or employer

Rule governing procedure to be followed by a specialist or consultant engaged by an insurance carrier or employer

After completing its work on the rules the committee presented them to the Industrial Council in regular session and recommended their adoption. The Industrial Council voted unanimously in favor of the rules, and on the advice and recommendation of the council, the Industrial Commissioner promulgated and adopted the Rules and Regulations which are now in effect.

The sub-committee has heard many appeals by physicians who were not satisfied with the ratings on qualifications assigned to them by the various medical compensation boards. On

the majority of these appeals, however, it was found that the ratings and qualifications given these physicians were proper and correct and those physicians who attended hearings before the committee, were in most instances convinced of the fairness of their rating, and the rulings of the Medical Compensation Boards were invariably sustained.

Many attempts have been made to solve the vexatious problem of the securing of authorization in operative cases. The law is not clear on this point, merely stating that if the authorization is withheld, the Commissioner should be appealed to. It is obvious that the Commissioner has no facilities for making such a decision nor will he assume either the medical or financial responsibility. The Committee, therefore, has taken the position that the doctor and hospital must act on their own responsibility and take the financial risk if the compensation claim is proven non-compensable. The Industrial Council and the Industrial Commissioner entertains the same view on this question.

The enforcement of the payment of medical and hospital bills by non-insured employers has caused great annoyance as the law is devoid of any enforcement or penalizing provision. The Industrial Board has ruled that it is without any authority or jurisdiction in this matter.

On receipt of complaints from physicians and hospitals about the non-payment of their bills by these employers, the Medical Registration Unit writes letters to these employers demanding payment of the bills. These letters demanding payment has resulted in the payment of many of such bills.

It is obvious that an amendment to Section 13 must be added containing an enforcement provision to compel payment of medical and hospital bills on cases where the employer failed to carry Compensation insurance.

The sub-committee submitted such an amendment to the Industrial Commissioner last year who presented it to the legislature for passage but the bill remained inactive in committee.

A number of physicians were denied recommendation for authorization by the various medical compensation Boards and these physicians filed appeals with the Industrial Council.

The sub-committee gave considerable time and consideration to the hearing of these appeals and presented the facts and its recommendations to the Council, sustaining in some instances the findings and decisions of the medical compensation boards and in a few instances recommending authorization.

The sub-committee from time to time was confronted with legal issues relating to the various provisions of the Act, and was instrumental through the Industrial Commissioner in securing several opinions rendered by the

Attorney General interpreting the law on the following points

Opinion defining the nature of evidence necessary to sustain a charge of solicitation

Opinion defining the rights, duties and limitations of the sub-committee in its relation to the Industrial Council

Opinion upholding the right of the Industrial Commissioner to charge a license fee to any town, city or municipality in the state covering the operation of a medical bureau

Opinion defining the extent of authority to be used by medical compensation boards and the latitude allowed in considering applications filed by physicians

Opinion indicating that lay owned or incorporated x-ray laboratories seeking licenses must be given consideration and acted upon as such provision is included in the law

Opinion indicating that the law fails to provide any penalty for imposition against a physician for treating injured employees without the authorization of the Industrial Commissioner and suggesting that the law be amended to provide that a violation of any of the provisions shall constitute a misdemeanor

Opinion indicating that the clause contained in the physician's application blanks purporting to waive certain rights of the applicant shall be eliminated

Opinion indicating that insurance carriers and employers shall pay all bills submitted by public hospitals in the City of New York which include services rendered by physicians because of a clause which appears in the City Charter which provides that such physicians "shall serve without compensation"

Opinion indicating that compensation x-ray and diagnostic laboratories may submit bills direct for services rendered by physicians employed by them

Opinion indicating that all bills for treatment rendered by physicians outside of the state, and which are contested by the carrier or employer must be referred to the medical bill calendar of the Department for consideration as the amendment to Section 13 does not apply

Opinion indicating that all appeals filed with the Industrial Council from the decisions and findings of the Medical Compensation Boards must be considered and passed upon by the Council, and that such matters may not be referred back to the Medical Boards

Opinion defining the authority of the Industrial Commissioner in adopting and promulgating rules regulating insurance carriers recommending authorized physicians to their policy holders and the procedure to be followed by medical inspectors and consultants employed by them

Opinion indicating that it is not necessary to be listed on the panel of authorized physicians for those who merely make physical examinations and give testimony for claimants at hearings, that the claimant may pay for such services, that only physicians as render treatment are stopped from receiving fees from claimants

Opinion indicating that the amendment to Section 13 does not apply to dentists, that the status of a dentist in compensation cases is the same as it was prior to the amendment.

The sub-committee also assisted the committee on rules for arbitration of medical and hospital bills composed of representatives of state and county medical societies and the Compensation Rating Board, which acts for the insurance carriers

A set of ten rules was adopted and established by this committee governing the procedure to be followed in the arbitration proceedings

The subjects covered by these rules are as follows

Rule indicating the method of filing objections to medical bills by insurance carriers and the time limitation

Rule indicating the form and the manner of filing a claim by a physician for improper transfer of treatment.

Rule indicating that the Medical Society and the Rating Board shall jointly prepare a calendar of cases and arrange time and place of hearing

Rule indicating the manner of selection of arbitrators

Rule relating to notices to interested parties on arbitration hearings

Rule indicating the form of agreement to arbitrate, to be signed by all parties in interest.

Rule providing for a recording clerk to make notes of the proceedings, and to administer the oath to the arbitrators

Rule providing for a two dollar minimum deposit by the claimant physician and the procedure to be followed in conducting hearings

Rule providing that all decisions be signed and acknowledged by the arbitrators and the method of mailing the decisions

Rule providing the manner in which the five per cent charge shall be collected from each litigant and the payment of a ten dollar *per diem* fee to each arbitrator

The set up is now complete and the machinery has been set in motion for the prompt arbitration of medical and hospital bills. The Medical Registration Unit has finished the checking of and the segregation of medical and hospital bills according to County and carrier. There are about twenty-five hundred bills which have been submitted to the Compensation Rating Board for the purpose of arranging calendars of hearings and the setting of the date, time, and place of such hearings

Under the provisions of the amendment to Section 13, the Industrial Commissioner organized a new unit in the Department of Labor known as "the Compensation Medical Registration Unit"

The work accomplished by this Unit from the date of its inception—July 1, 1935 to December 31, 1936—is indicated in the following statement

Annual Report of the
Compensation Medical Registration Unit
for the Calendar Year 1936

Number of physicians authorized—New York District	9,094
Number of physicians authorized—Albany District	1,431
Number of physicians authorized—Buffalo District	1,107
Number of physicians authorized—Syracuse District	1,218
Number of physicians authorized—Rochester District	953
TOTAL	13 803
Number of Medical Bureaus licensed	59
Number of Medical Bureaus approved	77
Number of Medical Bureaus withdrawn	1
Number of Medical Bureau applications pending	243
Number of Medical Bureaus refused.	29
Number of Medical Bureau licenses applied for	350
Number of Laboratories licensed	None
Number of Laboratory licenses applied for	7
Number of Laboratories approved	None
Number of Medical Bureau license fees paid	134
Total amount paid for Medical Bureau licenses	\$6 700 00
Number of Laboratory license fees paid	4
Total amount paid for Laboratory licenses	\$40 00
Number of Medical bills to be set for Arbitration Committee hearing	2 274
Number of hospital bills to be set for Arbitration Committee hearing	
Number of hearings held by Arbitration Committee	None
Number of Medical bills protested and adjusted without arbitration	1,691
Number of hospital bills protested and adjusted without arbitration	153
Number of Medical bills held pending receipt of further information	1 704
Number of hospital bills held pending receipt of further information	56
Number of self insurers' bills held pending receipt of further information	22 4
Doctors bills	
Hospital bills	
Number of no-insurance cases held pending receipt of further information	168
Doctors bills	
Hospital bills	
Number of self insurers bills adjusted	11
Doctors bills	28
Hospital bills	
Number of no-insurance cases adjusted	1
Doctors bills	42
Hospital bills	

The sub-committee has many other problems which have been presented to it for consideration and advice, some of which are listed below

Minimum medical fee schedule relating to upstate New York.

Hospital fee schedule.

Modification of physician's application blank

Consider many appeals recently received from employers from the decision of the medical compensation boards denying licenses to operate medical bureaus

Consider several requests from a few large employers for a modification of the fee schedule to apply in their particular plants because of the frequency of accidents

Arrange for a meeting with the Industrial Commissioner, representatives of insurance carriers, self-insured employers and insurance buyers to ascertain their actual experience resulting from the amendment to Section 13 and to secure the viewpoint of all interested parties relating to the medical situation as it exists at the present time The Industrial Commissioner has indicated his intention to secure from insurance carriers and self-insured employers comparative statements of medical costs covering the period of one year prior to the amendment to Section 13 and a like period subsequent to the amendment for discussion and consideration at this meeting

This brochure contains a complete recording of the more important questions that needed consideration and clarification for the proper administration of Chapters 258 and 930 of the Laws of 1935

Respectfully submitted,

talk on the latest research news concerning vitamins

Professional friends interested in dietetics are invited to the six-thirty dinner (\$2 50 per plate) or to attend the lecture scheduled for eight-thirty which is open to the profession Informal dress

PNEUMONIA CASE REPORTS

That the physicians of the State may have concrete examples of different phases of anti-pneumococcus serum treatment of pneumococcus pneumonia, there will appear here case reports selected from the large number received by the State Department of Health on the use of anti-pneumococcus serum produced and distributed by it

In order that physicians practicing in New York City or those using effective serum from other sources may also be represented, we hope that physicians who may have had particularly significant experiences with serum will submit short reports to the Pneumonia Editor, New York State Journal of Medicine, 33 W 42 Street, New York City—Editor

Report from the records of John H. Nugent, M.D., Southampton

"A man, sixty-eight years of age, developed symptoms of an acute upper respiratory infection on November 28. The following day there occurred the classical symptoms of pneumonia of sudden onset, a chill, pleurisy on the left side, blood-tinged sputum and a sharp elevation of temperature to 104°F.

"The patient was immediately taken to the hospital where sputum examination revealed the presence of Type I pneumococci and x-ray examination showed involvement of the entire left lung. The admission blood culture was negative, blood pressure was 200/100, pulse 120, respiration 28. The patient was markedly prostrated and quite delirious. Because of his age, marked pulmonary involvement and the existence of previously recognized chronic nephritis and myocarditis, the prognosis was considered very poor indeed.

"There was no history suggestive of allergic tendencies and both the intradermal and ophthalmic tests for horse serum sensitivity were negative so that serum treatment (concentrated antipneumococcus serum Type I, New York State Department of Health) was instituted with the least possible delay.

"At about 6 P.M., November 29 (the day of onset) one c.c. of serum diluted in a small volume of salt solution was administered

very slowly. This was well-tolerated and at 7 P.M. thirty-nine c.c. of concentrated serum were given. At 10:30 P.M. forty c.c. more were administered. The temperature commenced to fall following the second large dose and by 8 o'clock the following morning (2nd day of the illness) it had reached 102°F from which it fell more gradually to 100 during the next twenty-four hours. The fall in temperature was attended by general clinical evidence of improvement.

"The convalescent course was complicated by a short period of postpneumonic delirium but was otherwise uneventful. The patient was discharged from the hospital at the end of three weeks having made a complete recovery.

"The general treatment received by the patient was routine and supportive. It was felt that the serum in this instance had proved a specific remedy."

Dr. Nugent's case has been selected to illustrate the effective use of serum in the treatment of a case with an obviously grave prognosis. On the unfavorable side must be placed the age of the patient, the presence of a serious complicating condition, a very rapidly spreading infection and poor clinical condition. On the favorable side, in addition to the proper general treatment, are the facts that the patient sought medical care on the first day of his illness and that an adequate amount of serum was administered with the least possible delay.—Editor

Antipneumococcus Serum, Type II

Now Distributed by the New York State Department of Health

The distribution of concentrated anti-pneumococcus serum, Type II, was officially undertaken by the Division of Laboratories and Research of the New York State Department of Health on January 1, 1937. Because of the limited supply available, it is not possible to provide with Type II serum all of the district laboratory supply stations now maintaining Type I serum. In addition to the central laboratory in Albany and the branch laboratory in New York City, twenty-four local stations have been selected, mainly in the larger cities and in certain localities where there has been the greatest demand for the type I serum during the past year. The supply in each sta-

tion will be limited so that as small an amount as possible will be inactive, the remainder being held at the central laboratory for shipment. As more serum becomes available, additional stations will be supplied, especially those where an increased incidence of type II cases is indicated.

The concentrated type-II serum diluted with physiological salt solution in order to reduce the protein content and to facilitate slower administration, is distributed in packages of 20,000 units contained in twenty-four c.c. A dosage of from 160,000 to 200,000 units is advised as usually adequate for the treatment of a case although in certain instances an additional amount will be found necessary.

SOCIETY FOR THE PREVENTION OF ASPHYXIAL DEATH

Pneumatology

During the last ten years, the use of gases for therapeutic purposes has become increasingly important. The technician who delivers and operates oxygen therapy equipment in the home and in the hospital is a familiar figure. The highly trained rescue squads of the Police and Fire Departments, the Industries, and the Utilities whose technicians employ gases for the saving of life operate separately and appear in no way related either with the Oxygen Therapy group or with the quasi medical technician who administers gases for the control of pain. Each group, completely isolated one from the other are directed by medical personnel, having as little in common, i.e., the Internist, the Police Surgeon, the Anesthetist.

The bond of common interest, the common denominator, the factor which integrates these separate activities into a single work, namely the use of gases for therapeutic purposes to treat disease, to save life, to control pain, appears to have been entirely overlooked.

Granting the existence of this state of affairs, and assuming the desirability of uniting these scattered activities, at least from the standpoint of the dissemination of knowledge and the accumulation of experience, we may well ask the reason why these activities have not been united and offer a suggestion by means of which they may be brought together.

That the situation is recognized and is being met in a number of Universities and Hospitals by forward-looking physicians in charge of Departments of Anesthesia, who offer the services of this Department to care for the administration of gases, but serves to bring into relief a fundamental difficulty which by its very nature retards such a desirable integration. We refer to the restriction imposed upon the physician by the terminology, "anesthesia," the control of pain. Why should a physician whose specialty is limited to the control of pain, by reason of this calling, be requested to care for asphyxia neonatorum, carbon monoxide poisoning, submersion, terminal polio, or be asked to treat anoxemia due to acute pulmonary infection, or to cardiac decompensation? Is it not too much to expect that the nature of anesthesia is so generally understood that the ability of the anesthetist to treat asphyxia

is implied? Does not the terminology, "anesthesia" serve as a definite resistance to any effort which may be made to relieve the situation?

While a rose by any other name may smell as sweet, yet without a commonly accepted generic term, the horticulturist would promptly be brought to a standstill. Is it not greatly to be desired, therefore, that a descriptive generic term, to include the specific activities, now known as anesthesia, resuscitation and oxygen therapy, be promptly adopted.

In a search for such a term, among those responsible for the nomenclature of disease, the following terms have been suggested: Inhalational Therapy, Asphyxial Medicine, Apnotherapy, Aeriotherapy, Aerotherapy, and Pneumatotherapy.

The term selected should have a sound derivation, a certain familiarity in appearance and lend itself to an elaboration to cover the science, the technic, and the technical personnel.

Inhalation Therapy and Asphyxial Medicine do not lend themselves to accepting the suffix, "ology, or science." Aerotherapy and Aeriotherapy while descriptive of the use of gases for therapeutic purposes savor too much of aeronautics. Apnotherapy, signifying breathlessness, lacks familiarity. Pneumatotherapy remains, is suggestive, derived from the correct roots and suggests inclusiveness. "Pneumon," lung, and "pneumatics," the science of gases, is covered by the scientific term, "pneumatology," which is readily expanded into "pneumatotherapy" and "pneumatological technician."

Should "pneumatology" be found acceptable, it would include as a generic term, the specific activities referred to as anesthesia, resuscitation, and oxygen therapy. The objection that anesthesia includes also the use of local, conductive, rectal, and intravenous methods may be met by the fact that at least eighty per cent of all anesthetics administered are brought about by the use of such gases, as nitrous oxide, oxygen, cyclopropane, ethylene, ether, and chloroform—the vapors of the last two being regarded as gases, in practice. It is to be expected that the personnel engaged in the field covering the larger volume of patients, and providing routine material as well as a wide experimental background,

namely, anesthesia should provide the personnel from which the pneumatologist would be evolved. The pneumatologist would radiate instruction and control over the nonmedical personnel now engaged in the administration of anesthetics, oxygen therapy, and in resuscitation. The pneumatological technician would fall into his natural relationship to medical direction and

control. Owing to the scope of the field, the present competition existing between the technical and the medical group would be automatically eliminated.

As the first step, therefore, in the coordination of the disorganized field of gas therapy, which now exists, the acceptance of the generic term, "Pneumatology" is proposed.

EVILS OF CONTRACT PRACTICE

Contract practice, in this country, was born of geographic and social necessity. When certain pioneering industries, such as mining, lumbering and construction work, pushed beyond established settlements, such industries were obliged to provide whatever medical facilities were supplied to such isolated communities. This service varied widely in quality but was better than none.

Most modern types of contract practice lack this excuse of necessity. Instead of meeting a lack of facilities in an isolated locality they compete with adequate facilities already established. The motive of establishment is not the benefit of those receiving the service but the possibility of financial gain to those contracting for the delivery of the service, says the *AMA Journal*. Contract systems are now operated more often to reduce compensation costs, absenteeism, labor turnover, inefficiency and wage payments than to supply needed medical service.

This conclusion as to motive is justified by certain facts. The contract plans do not add to existing services. The features for which their founders fight hardest are those most profitable to industry but not always most helpful to the patients. The managers of the plan insist on choosing the physicians. This choice is determined more by the amounts paid physicians, the character of the medical testimony that will be given in damage suits and compensation cases, and ability to keep down costs than by professional qualifications or devotion to the patient's welfare. The patient is given little or no choice, the most desirable ethical practitioners in the community usually refusing to enter the contract group from which the patient must choose. Contract practice is at present almost universally accompanied by advertising, commercial bargaining, underbidding, subletting, coercion or plain racketeering, and all of these are

destructive ingredients in medical service.

If these flagrantly undesirable commercial features could be eliminated, the result of injecting contract practice into the present system of medical practice would still be injurious to the general character of medical service. Contract practice always is restricted to a selected group—generally of adult employees. It leaves uncared for the mass of children, aged, women, unemployed and those most in need of medical service. Such an exclusion, by reducing the field of private practice, inevitably lowers the quality of care it is possible to give to those outside the contract scheme. By thus lowering the standard of medical service in the field with which contract practice must be compared, this situation tends in turn to lower the standards that will be maintained under contract.

Contract medicine is almost exclusively curative medicine. It gives little attention to prevention. The amount of work demanded of each salaried physician is usually so great that he has little time for immunizations and other preventive measures. The restricted coverage makes it impossible to reach the children and others most in need of preventive service. The isolated group character of contract practice does not encourage the contract physicians to become interested in preventive work for an entire community.

Contract practice is so prone to a certain set of defects that they may almost be said to be inherent. Insufficient pay to overworked physicians encourages superficial service. When financial considerations such as compensation are dominant, incidents have been recounted in official investigations of unnecessary amputations to insure an earlier discharge and release from compensation payments, and the use of untrained laymen in giving medical care.

PAN AMERICAN MEDICAL ASSOCIATION

The Future of Pan American Medicine

Dr Kellogg, President of the New York Chapter, Dr Eller, Director General of the Pan American Medical Association, Dr Heyd, President of the American Medical Association, Dr Irving, Secty of the Medical Society of the State of New York, Dr DeSanctis, President of the County Medical Society of New York, Dr Ewing, Director of the General Memorial Hospital, New York, Dr Lewis, Professor of Surgery, Johns Hopkins University, Baltimore, Dr Alessandrini, Professor of Surgery, University of Chile, Santiago, Fellow members of the Pan American Medical Association and distinguished guests

It is a great honor and a cause of gratification for me to be able to address this distinguished group of my colleagues gathered here, both to do homage to that science, the flame of which we strive to carry forward, and to pay tribute to closer international relations and to the furtherance of that great idea of Pan Americanism so dear to the hearts of Simon Bolivar and San Martin

Characteristic of the growing solidarity among the physicians of the Western Hemisphere is the cordiality with which visiting physicians from Latin America are received by the officers and members of the Pan American Medical Association. So many Latin American physicians visit the hospitals and clinics of the United States that at times we fear that it is too much of a burden on our fellow members of the Association. Despite these great demands they have shown us every attention, and have given unstintingly of their time to arrange conferences with outstanding physicians and demonstrations of medical activities. We physicians of Latin America deeply appreciate this friendly and brotherly attitude, and you may be sure that we shall be equally diligent in these matters when you visit our respective countries. To speak for my Argentine colleagues who are present, as well as for myself, we will always cherish the memory of your generous hospitality and of our comradeship with you.

I am indebted not only to my colleagues of New York for their hospitality, but also to those of many other cities, especially for invitations that I have received from the

Chapters of the Pan American Medical Association in Philadelphia, Washington, D C, Chicago, Rochester, St Louis, Los Angeles, and San Francisco, as well as from other medical organizations. I fervently hope that the fraternal relationship so fully expressed in these invitations and in this gathering, may be indicative of the early development of a great "esprit de corps" among all physicians.

The distrust and uncertainty prevailing among the nations of the Old World are causes of deep anxiety and regret. For this reason it is all the more important that the nations of the New World should work in closer harmony to improve world conditions. Who knows but that perhaps our example and our success may serve as a guiding light for world conditions. Exemplified here tonight are the international cooperation and international friendship that is so necessary to solve the troubles of a sick world.

There is no profession which brings one closer to man and his family than the medical profession. Therefore, the physician can be a great and good influence on the people of his country. He can instill the ideals of international cooperation.

The practice of medicine should have no religious barriers or national boundaries. The care of the sick and the improvement of sanitation should be a collective responsibility of all nations. Therefore, international understanding and cooperation cannot be furthered better than through the field of medicine.

The Pan American Medical Association believes in the just and generous principles of Pan Americanism and in their power to advance the cause of human happiness throughout our hemisphere. These are the ideals to which we willingly dedicate the best efforts of our minds and hands. Speaking for my colleagues in the Argentine, I can assure you that we will cooperate with our best ability and strength.

The Pan American Medical Association looks back over eleven years of fruitful existence. During these years international medical congresses have been held in Havana, Panama City, Mexico City, Dallas (Texas), Puerto Rico, Rio de Janeiro, Sao

Address given by Dr José Arcé at a dinner given in his honor at the Metropolitan Club, New York City, January 11, 1937, by the New York Chapter of the Pan American Medical Association. Dr Arcé is Professor of Surgery and Dean of the University of Buenos Aires and President of the Argentine Chapter of the Pan American Medical Association.

Paulo, Brazil, and Venezuela. The next congress will begin on New Year's Day, 1938, at Havana, and I hope that all the physicians here tonight will be present, either as contributors of scientific papers or for the purpose of discussing the views of their colleagues from the three Americas. I plan to be present and I am sure that many of my colleagues from the Argentine will join me.

The purpose of these congresses is to blend the best practical medical thought and progressive ideals with the cultural influences of international contacts, reinforced by world-wide knowledge of the achievements and needs of the human race. They bring together, from all parts of the New World, men and women in various specialties and afford numerous opportunities for the presentation of the newest and best in medicine. As the eminent physician and former president of this Association, Dr. Chevalier Jackson, stated: "The Pan American Medical Association has no political, racial, religious or commercial aims. It is purely a scientific body of medical men. It is intended only as a means of discussion and of effort toward the solution of many problems of medical science."

It would be most inaccurate, however, if I created the belief that occasional congresses are the outstanding factor in the work of the Association. On the contrary, its activity is continuous. It is an international organization with chapters in many cities in the United States and in the twenty-one other countries of the Western Hemisphere. Scholarships are now being granted to graduate physicians enabling them to come to the United States for postgraduate study. As resources increase, it is proposed to give twenty-two such scholarships annually, one to a physician from every country in this hemisphere.

Most of you are acquainted with the plans of the Pan American Medical Association to promote postgraduate medical centers in the larger cities of the Western Hemisphere. The first of these institutions will be erected in New York, and I can say that Argentina will do everything possible to follow with a similar center as soon as possible. In these institutions physicians will be able to obtain instruction in all branches of medicine and surgery. Arrangements will be made to house the scholarship students. An important feature will be to have exchange professorships.

We realize that this project is a gigantic one, and will require tremendous efforts for achievement. However, the contributions to humanity which will result from

the fulfillment of such a creation makes it worthy of the cooperation of every single physician in the West Hemisphere.

No time could be more opportune for the realization of this project. Political conditions prevailing in European countries have resulted in a deterioration of the scientific values which were a credit to these countries in the past. Students are now looking to the Americas for scientific instruction, and we now find a steady flow of students here and proper provision should be made to accommodate their needs.

Such being the case, nothing could be more desirable than to have in New York the first great Pan American Post Graduate Medical School and Hospital, which is to be followed later by similar institutions in the Argentine, Brazil, Mexico, etc. During the last forty years, the United States has been able to draw to itself the best scientific investigators of the world, and today it finds itself moving beyond the achievements of its former mentors.

It is indeed inspiring that your distinguished President Roosevelt has, in a conference with your Director General, enthusiastically endorsed the plan of the Pan American Medical Association to create post graduate teaching centers in the different American republics. It is equally inspiring that the governments of all the Americas have expressed similar approval and support.

The people of this and other American nations should appreciate the work of the Pan American Medical Association. The efforts which are being put forth by the Directors of the Association are most worthy of praise, and I wish particularly to commend the work of the Director General, my great friend, Dr. Joseph Jordan Eller. We all realize that the tremendous energy and the foresight of this modest fellow have carried the Association from a small and unimportant one to the place of great importance it now holds in our twenty-two countries. We also happen to know that he has been unselfish with his time and money for the cause, his hospitality and friendly interest in the needs of the physicians visiting here are true examples of the spirit of Pan Americanism. The success of the cruise congresses, both scientifically and socially, was due in large measure to his efforts. His ability to make warm friends among important men in and outside of the medical profession gives great promise of his getting the support necessary for endowing the Pan American Post Graduate Medical School.

We physicians in the Argentine have been carrying on the ideals and purposes of the Association by promoting annual meetings in Buenos Aires, Montevideo, Rio de Janeiro, and Santiago, by receiving physicians of other Latin American countries as our guests and associates, and by sharing with them all the means of research at our disposal.

The Faculty of Medicine of Buenos Aires is about to construct a new and magnificent building for its headquarters, and it gives me satisfaction to announce in advance to you that it will have room for research activities available to the doctors of Argentina and of other American nations who may wish to go into the experimental field or to perfect their knowledge. Thus in Latin America also, physicians are taking a leading part in the virile and positive

spirit of progress toward complete international cooperation.

I cannot close my address without paying tribute to the memory of the late Dr Harlow Brooks, one of the world's great physicians and one of the great exponents of human fellowship. He was a former trustee of the Pan American Medical Association and a very dear friend of all of us. In commemoration of the true Pan American spirit which he had, and the work done by him for the Association from its inception, we have planned to create a fund in the Association to be known as the "Harlow Brooks' Memorial Post Graduate Medical Scholarship."

To all of you I give the good wishes of the people of my country, of my colleagues, and of myself. I thank you!

ARRESTS MADE IN THE 'EYESWINDLING RACKET'

The U S Post Office Department, according to the *Journal of the A.M.A.*, has made the following arrests in its investigation of the "eyeswindling racket," also known as the "glimmer racket," which has been carried on throughout the country for several years.

Boyce Bateman, Harold N Baxley, Samuel Birnstein, Samuel Bluestine, Iddien Reese Conner, Herbert C. Crangle, Lewis Fenburg, Samuel F Freedman, John Gray, William E. Hanecy, Harry Herman Holtkamp, Lawrence B Holtkamp, Lewis Levy, William Henry Londergon Jr, Frank Mackett Jr, J C. Murphy, Edward Robinson, alias Eddie A. William Shapiro, Jerry Theeman, Elliott George Wilkinson, Mathew O Wilkinson and Curtis J Yeager.

All have been charged with violating either federal or state laws in the operation of the racket. The *J.A.M.A.* published a news item concerning Birnstein, November 14, page 1643. Bluestine was sentenced to one year in jail. Gray was sentenced to ten years on the eyeswindling scheme and fifteen years for attempted murder in the penitentiary at Huntsville, Texas. Murphy received a sentence of five years in the Huntsville prison. Crangle was arrested November 7 and removed to Norfolk, Va., where the indictment is pending. Londergon, said to be a resident of Chicago, was arrested in Carroll, Iowa, November 21, and sentenced at Montezuma, November 30, to serve seven

years in the penitentiary at Fort Madison. Robinson also was arrested at Carroll, November 21, and held for removal to Asheville, N C, where he is wanted on a federal charge in connection with a swindle in that state.

In addition to the eyeswindling charge placed against these "fake eye specialists," the government has also accused them of using the mails to defraud. Three indictments have been returned against Mackett and others. The swindlers sent to Mackett the checks which they obtained from their victims and he deposited them in banks for collection, remitting the proceeds, less ten per cent commission, to the swindlers.

Mackett is an attorney in Milwaukee and in addition operates what is known as the Police and Sheriff's Association of America. In the latter operation he sends agents throughout the country to call on police chiefs and sheriffs and induce them to join his association, giving them free accident policies and in return procuring from the chiefs of police and sheriffs letters which are used in the solicitation of advertisements from the bank and business houses. Hanecy, indicted with Mackett in the collection of the checks, is also a lawyer.

The postoffice department states that more than 100 men have been engaged in the "glimmer racket."

Paulo, Brazil, and Venezuela. The next congress will begin on New Year's Day, 1938, at Havana, and I hope that all the physicians here tonight will be present, either as contributors of scientific papers or for the purpose of discussing the views of their colleagues from the three Americas. I plan to be present and I am sure that many of my colleagues from the Argentine will join me.

borne in mind that a patient may be suffering from one or more of the other known venereal diseases at the same time. It is not rare to find a patient whose history suggests that he was infected with syphilis, gonorrhea, chancroid, and lymphogranuloma inguinale simultaneously. It is therefore important not to overlook any of them.

General Statement

Lymphogranuloma inguinale is a venereal disease of inflammatory origin. The etiological agent is probably a filtrable virus. This virus may be transmitted experimentally to a number of animal species. The onset in humans is characterized by a small initial inoculatory lesion usually on the genitalia but may be elsewhere. This is followed by an inflammatory swelling of the regional lymph nodes, with involvement of the adjacent connective tissue and lymphatics. In the majority of cases multiple small foci of necrosis and suppuration occur within the lymph nodes. Constitutional symptoms appear, which include lassitude, fever, sweats, anorexia, loss of weight, transient rash, and arthralgias. The adenopathy in males generally is localized to the inguinal or inguocrural-iliac group of glands, giving rise to the inguinal bubo. In females the localization of the infection generally takes place chiefly in the intrapelvic glands and the subsequent inflammatory and cicatricial reaction set up in the endopelvic fascia leads to the genito-ano-rectal syndrome.

Initial lesion. A history of the initial lesion is obtainable in a minority of cases seen. The nature of the lesion is described as a papule, vesicle, small ulceration about the corona or a herpeticiform lesion on the shaft of the penis. A history of a urethritis which is nongonorrheal is likewise present occasionally. The initial lesion usually heals spontaneously. There are many cases, however, in which the primary lesion increases in size, breaks down, and forms chronic ulcerations which resemble chancres, chancroids or epitheliomata. This group of chronic primary lesions makes up a distinct division among the cases observed.

In women, the acute primary lesion appears as a small ulceration of the cervix or fourchette. The lesion is evanescent and usually heals spontaneously. It causes little or no discomfort and on that account is often overlooked by both patient and physician.

Distribution. The disease occurs more frequently among the colored and Porto Rican groups. The incidence among men appears to be greater than in women at

present. However, many white women have been observed with open lesions. A majority of white men infected give a history of sexual contact with a negress. The average age of the patients observed is about thirty years. The youngest case is nine years old, a Porto Rican female child. The oldest was a sixty year old white male.

Incubation period. This cannot be determined accurately. A probable time interval of between two to ten days may be considered as likely. In most of the cases where the primary lesion heals spontaneously the healing takes place within two weeks. The glandular enlargement occurs within four days to three weeks after the appearance of the initial lesion. The glands break down in about sixty per cent of the cases within three weeks after the enlargement is noted. The enlargement of the iliac glands can be made out in the majority of the cases.

The Frei test. The Frei test becomes positive about nine days after the infection has taken place and remains positive even after numerous attempts at desensitization.

Signs and Symptoms. The genital lesions in the male and external genital lesions in the female are obvious. However, the cervical lesions in the female and rectal lesions in both male and female may be observed by speculum examination and proctoscopy. The rectal lesions are usually secondary to a previous lymphatic involvement. They may, however, be primary and are observed in cases of pederasty. The rectal lesions may appear as early as six weeks after the onset of the primary lesion as an acute fulminating proctitis, or come on insidiously as a fibrous stricture without any symptoms twelve years after the primary lesion.

Pathology. A pathologic correlation of the histologic findings in all of the three clinical groups mentioned above has been made. The histologic lesion of the inguinal nodes although not pathognomonic, is considered suggestive and sufficiently characteristic for diagnosis. The lesion consists of an inflammatory nodule having a peripheral shell of epithelioid cells arranged in a palisaded manner. The central core is filled with inflammatory elements. Giant cells of the Langhans type may be present in the peripheral zone later in the disease. As the disease progresses the center undergoes necrosis, while in the periphery, accumulations of fibroblasts and plasma cells dominate the picture.

Histologic examination of the pelvic glands removed at autopsy showed lesions

LYMPHOGRANULOMA INGUINALE

BORRIS A. KORNBLITH, M.D., *New York City*

On November 17, 1936 the Department of Health of the City of New York inaugurated a new service to physicians in private practice, to hospitals, and clinics. This service consists of a clinic which will be devoted to the diagnosis of lymphogranuloma inguinale.

The Frei test is the most important means of establishing a diagnosis of this condition. This test is performed by the intradermal injection of 0.1 cc of suitably treated test material. The result is read forty-eight hours after injection. A positive reaction consists of a small (5-8 mm) tender nodule in the skin with an erythematous peripheral zone about one cm in diameter, which persists for one week or longer. A negative reaction leaves the skin entirely unaffected. The point of the needle puncture in the skin may possibly be seen, but within eight hours after injection the injected material is entirely absorbed leaving no trace locally.

The specificity of the Frei test has by this time been well-established. When a positive test is present, the patient either has lymphogranuloma inguinale at the time the test is performed, or has had the disease at one time or another. A positive Frei test may be elicited for many years possibly throughout life after infection has once taken place.

In introducing such diagnostic facilities, it is important to designate the type of clinical case which will be suitable for investigation. Cases which should be referred for a Frei test embrace a number of previously known clinical entities, all of which are recognized at present as likely to give a positive reaction to the Frei test. All these conditions which show a positive test may now be grouped under a single heading of lymphogranuloma inguinale. Lymphogranuloma, clinically, can appear as any of the following:

Genital Lesions

- 1 Herpes progenitalis
- 2 Multiple papular or chancroidal lesions about the corona
- 3 Paraphimosis with evanescent small ul-

cerative lesions at the frenulum (acute and chronic)

4 Chronic progressive ulcerative lesions of the glans penis or shaft of the penis (lymphogranuloma inguinale chancre)

5 Elephantiasis of the scrotum and penis or vulva

6 Chronic ulceration of the vulva especially the fourchette or cervix

7 Chronic pelvic fistulae

8 Rodent ulcer of the vulva

9 Elephantiasis of clitoris

10 Pelvic inflammation of obscure origin

11 So-called cases of esthiomene.

Glandular Lesions

1 Inguinal adenopathy (inflammatory) of obscure origin

2 Generalized lymphadenopathy resembling infectious mononucleosis

3 Pelvic lymphadenopathy

4 Extragenital lymphadenopathy of obscure origin with possible primary lesions on the tongue or hands

Rectal Lesions

1 Rectal stricture (inflammatory)

2 Anorectal syphiloma

3 Inflammatory lesions of the rectum and anus i.e. chronic and acute proctitis and proctitis, fistulae in ano, rectovaginal fistulae

4 Perianal condylomata

5 Localized ulcerative colitis of lower sigmoid and rectosigmoid

Since the disease in question has a definite venereal origin, laboratory tests to exclude other known venereal diseases are obligatory. A Wassermann test, darkfield examination of any open lesions, a smear for Ducrey bacilli, a smear for gonococci, and bacteriologic culture of purulent material aspirated from inguinal buboes are all indicated. Where a diagnosis is still uncertain, a biopsy of the local lesion, guinea pig inoculation of aspirated pus or massaged gland, and smears stained for tubercle bacilli may be done. It must be

Secretaries of County and local Medical Societies are requested to send the programs of coming meetings to this department one month in advance, for the information of members who may be interested

Broome County

AT THE MEETING OF THE Broome County Medical Society on Jan 12 a testimonial dinner was given in honor of Dr Henry D Watson, Secretary Emeritus, who has served as Secretary of this Society for a continuous period of twenty seven years. The speakers were Dr F M Miller, Dr S B Blakeley, Dr H I Johnston, Dr G C Vogt, "Travel Movies in Color," Dr F B Niles

Chautauqua County

The Chautauqua County Medical Society at the annual meeting in December at the White Inn, Fredonia, elected the officers for 1937 as follows

President, Dr W G Hayward, first vice-president, Dr C E Hallenbeck, second vice-president, Dr D W Buckmaster, secretary, Dr Edgar Bieber, treasurer, Dr F J Pfisterer. This will be Dr Bieber's twelfth term as secretary of the club

Motion pictures of various types of obstetrical procedure were shown by Dr E G Winkler of Buffalo

Chenango County

DR. EARL W WILCOX, coroner of Chenango County for more than twenty-five years, died at Chenango Memorial Hospital on Jan 6. He was sixty-five. He had been a practicing physician in Norwich thirty-five years. He was past president of the Chenango County Medical Society and a member of the staff of the Chenango Memorial Hospital

Columbia County

DR. CHARLES R. SKINNER, Secretary for many years of the Columbia County Medical Society, died at the Hudson City Hospital on Jan 1 of pneumonia. He was sixty-five

Delaware County

OFFICERS OF THE Delaware County Medical Society were elected at the annual banquet and business session in Delhi, December 15. Dr Doreen Corke was elected president, Dr Walter Eells, vice president, and

Dr Orin Q Flint secretary and treasurer. Eighteen attended the session

Erie County

DR. ARTHUR G BENNETT, prominent Buffalo eye specialist, member of the staff of half a dozen hospitals and professor emeritus of ophthalmology, University of Buffalo, died on Dec 28. He was seventy-six years old and had been ill several months, although he continued to practice during much of October

Hospital appointments include the staffs of Buffalo General, Deaconess, Lafayette General, Children's, City, Charity Eye and Ear Hospital, and the Craig Colony for Epileptics, Sonyea

Dr Bennett never ceased to treat the afflicted at various free dispensaries. There are hundreds of persons who, having been blind, now are able to see because of his professional skill

In 1893, Dr Bennett married Dr Alice Ross, also a graduate of the University of Buffalo, who practiced medicine as his associate for twenty-five years

Surviving Dr Bennett are his wife, a daughter, Mrs R Leslie Murray, and a son, Dr Arthur L Bennett, also an oculist, who has practiced for years with Dr Bennett

DR. JOHN A RAGONE, who as a children's specialist and pioneer in the use of heliotherapy in the treatment of tuberculosis achieved distinction, died of angina pectoris on Dec. 25 at his home in Buffalo. He was fifty-seven

Dr Ragone was a pioneer in maintaining child health in the schools and in the treatment of undernourished pupils as a disease preventive. He was credited with organizing in 1907 the first baby welfare service in the country

Dr Ragone was a member of the faculty of the University of Buffalo Medical school for twenty-nine years. He taught clinical medicine from 1907 to 1911, obstetrics from 1911 to 1917, and pediatrics from 1917 to the time of his death

Before embarking on his medical career, Dr Ragone established an enviable reputation as violinist and orchestra director

Greene County

THE JANUARY MEETING of the Medical

identical with those in the inguinal glands. Section through the Frei intradermal reaction showed a lesion similar to the ones mentioned above for the lymph nodes. It was thus observed that identical histologic features were present throughout all of these conditions, i.e. the inguinal, the pelvic, and skin lesions. All of these associated clinical entities thus find a common histologic correlation with their clinical counterparts. The histologic features of punch biopsy specimens of the rectal lesions and chronic genital lesions by themselves, however, were found inadequate for making any specific diagnosis except as they helped to exclude other known pathologic lesions, such as syphilis, tuberculosis, and carcinoma.

Laboratory findings The Wassermann

reaction in uncomplicated cases is negative. The Frei test is positive. The Dmelcos test is negative. Smears for Ducrey bacilli, gonococci, and tubercle bacilli are negative. Bacteriologic culture of the pus aspirated is sterile.

Treatment Numerous and varied methods of treatment have been reported with little success. Suffice it to say for the present that no standard method of therapy is available as yet, and that the general trend of treatment is toward the conservative side. The most encouraging results are now sought from specific biologic methods, i.e. the use of the Frei antigen as a therapeutic agent, used either intradermally, subcutaneously or intravenously. It is too soon, however, to recommend it for general use.

WATER, WATER EVERYWHERE

The fad for saturating the systems of patients with floods of water inspires a delicious flow of humor, without a dry line in it, from an Indiana medical man, Dr E O Harrold, of Marion, who takes his pen in hand and tells the editor of the *AMA Journal* all about it. His letter, in part, runs like this:

To the Editor—A few years ago I appealed to you as the fountainhead of information to know whether or not to give all my patients lots of physics. You did not reply but published my letter and I promptly received many replies from all over the country. Again my head is in a whirl. I find I am living in the center of the therapeutic Sahara Desert of the world. All of our patients are dehydrated, desiccated and destined to destruction. They are drying up. Water, water everywhere and every one short on water. It's a sad predicament. I find it a bit difficult to determine just how nearly my patients are about to blow away, but this difficulty does not seem to be shared by many others. A hospital patient who has not had an intravenous injection of fluid the first three hours after getting well settled down between his rubber sheets has probably just neglected to engage a physician. As the aquatic squad approaches a ward, the patients yell "Here come the Marines."

These hydration specialists have lots of backing. You can't read anything in medicine or the lay press without being informed that you should "push water." It's about the only remedy medicine offers that all the cultists have wholeheartedly accepted, so there must be a lot to it. Every time a country newspaper adds a new medical columnist, the town waterworks has to drill extra wells. Every time the schools adopt a new and up-to-date

physiology they have to add one or two fountains and some other plumbing. Some schools tried "water drinking drills" like fire drills but had to give them up because of shortage in facilities, and now we do not know and may never know whether it is safe to allow school children to face the future without these drinking drills. From my own children I learned that each child should become water conscious and react to the sight of a fountain very much as a dog does to a tree, except in reverse.

Every one knows that in case of a cold one should fairly swim in water. Since no one ever heard a fish sneeze, how can it be otherwise? Drinking lots of water for colds (with soda, apples or limes) always did look logical to me, for when your eyes, nose and lungs are spouting out pints of liquids it shows you are short on water or something. Besides, it seems reasonable to assume that if the water pouring out of these openings doesn't wash out the cold where it is, more water will start spouting elsewhere and wash it out where it isn't. Plenty of water in at the top and lots of physic from the bottom will often flush out a cold before it decides where to locate, fairly catching it in midair and totally off its guard. I'll admit that I have worried a bit about the effect to gravity on a very wet cold as compared to a dry one, and it hasn't always been clear to me how soaking up a cold till it drips will prevent it from extending itself rather aimlessly about *ad lib* and *cum laude*.

Even I admit that there are many instances when replacing lost or strayed fluids is highly indicated, but I have about arrived at the conclusion that there are a few other instances where the procedure is "the bunk" and I have definitely decided that thirst is a fair guide for water needs for one whose mind is clear and whose gullet is open.

their government with the Order of the British Empire. The ribbon was bestowed on her on the deck of the H M S *known* by the Prince of Wales, the present Duke of Windsor

Onondaga County

SEVENTY-FOUR REPRESENTATIVE CITIZENS of Onondaga county have been asked to serve on an honorary maternal welfare committee which will cooperate with the Onondaga Medical Society in a campaign to elevate the standards of maternity care and to reduce the maternal mortality rate in the county

The campaign will include professional educational activities, investigation of maternal mortalities, and a lay educational program.

The Onondaga Medical Society has completed a "refresher symposium in obstetrics" for practitioners in Onondaga county, and the fourth district branch of the New York State Nurses association is conducting a similar "refresher course" for private duty nurses

Ontario County

DR. WILLIAM WADDELL SKINNER of Geneva, seventy-six, one of the foremost physicians and surgeons in Western New York, died on Dec. 28

He was the pioneer surgeon in Geneva and for twenty years performed most of the operations there. He was consulting surgeon for Willard State Hospital and Geneva General Hospital

DR. C. W. GROVE, of Geneva, and newly elected officers of the Ontario County Medical Society, held the first meeting of the year on Jan. 12 in Canandaigua.

Dr. Arthur Hilton Paine, of Rochester, spoke on "Hematuria" at the scientific session.

St. Lawrence County

DR. HUGH A. GRANT, of Potsdam, who died on Dec. 16, was one of the Board of Directors of Clarkson College and was called the "father" of hockey at Clarkson, he was a director and staff physician of the Potsdam Hospital, and a director of the Citizens National Bank. The local newspaper says that he "has long been one of Potsdam's most capable and beloved physicians. To have Dr. Grant just enter a sick room seemed to restore the patient half way to health"

Warren County

DR. FRED GERSHOM FIELDING, a physician long prominent in the civic life of Glens Falls, died on Jan. 9 at his home, after a long illness. He was seventy

Dr. Fielding was one of the organizers of the Parks Hospital, and was active in the operation of the hospital for years. He became a member of the Glens Falls Hospital staff when it was organized and was president of the staff three years

He was a past president of the Warren County Medical Society and the fourth district of the State Medical Society

Westchester County

ORGANIZATION OF THE Yonkers Review Club, a group of younger physicians devoting their time to research work, is announced by the chairman, Dr. Amendes Al Morrone

The group is a unit of the Yonkers Academy of Medicine and includes fifteen members. The club plans to meet the third Tuesday of each month at the Professional Building

DR. CHARLES D. KAYSER, chief of the surgical staff of St. Joseph's Hospital, Yonkers, died on Dec. 31 at that hospital, where he had been a patient since Dec. 21, having suffered a paralytic stroke. He was sixty

Dr. Kayser had a large practice in Mount Vernon, Yonkers, and the North Bronx

At the time of the United States border trouble with Mexico, Dr. Kayser was a surgeon on the medical staff of the 71st Regiment. Later, when the United States entered the World War, he served as captain in the Medical Corps of the 105th Machine Gun Battalion, 27th Division, and saw service in France and Belgium. In addition to attaining the rank of major, he was decorated for bravery in the Battle of St. Souplet, in which he was gassed

THE YONKERS SOCIAL HYGIENE clinic treated 383 more patients in 1936 than in 1935, bringing the annual total to 8,625 persons, Health Commissioner Louis V. Waldron revealed at a session of the social hygiene committee of the Yonkers Tuberculosis and Health Association. Yonkers health and welfare leaders will attend a meeting sponsored by the Metropolitan Social Hygiene Council in New York on Feb. 3

Society of the County of Greene was held on Jan 12 at the New Saulpauugh Hotel at Catskill. Dr Eldridge H Campbell of Albany was the guest speaker and his topic, "The Diagnosis and Treatment of Common Thyroid Diseases."

Kings County

AT THE REQUEST OF THE Public Health Committee of the County Medical Society, arrangements have been made by the Brooklyn Tuberculosis and Health Association for a detailed study of all suspicious, active, and arrested cases of tuberculosis that were referred to private physicians during the high school chest x-ray survey, according to an announcement made over Station WBBC by Mrs Emma McLean, supervisor of health education for the association.

The purpose of the study, Mrs McLean stated, was to ascertain (1) whether the original diagnosis was subsequently confirmed, (2) whether adequate care has been provided and, if not, to assist in securing such care, (3) to visit home and school to check on mutual cooperation in helping to carry out physicians' recommendations, (4) to determine source of infection, if possible, and (5) to make a reasonably detailed sociological study of each case to ascertain whether common factors exist in a sufficiently large percentage to offer a clue to more adequate control of tuberculosis in the schools.

Madison County

THE RECENTLY ORGANIZED Women's Auxiliary of the Madison County Medical Society met at the Hotel Oneida on Dec 10 and elected officers as follows: President, Mrs Robert L Crockett, vice-presidents, Mrs J Frederick Rommel, Mrs Otto Pfaff, corresponding secretary, Mrs Robert H Ash, recording secretary, Mrs Richard Cuthbert, treasurer, Mrs Edmund L Finley, directors, Mrs Linn C Beebe, Mrs George F Mills.

Previous to the meeting the doctors and their wives had dinner and exchanged holidays gifts. Cards and bingo concluded the evening.

Monroe County

ON JANUARY 7 Dr Paul Dudley White, assistant professor of medicine at Harvard University and heart specialist, spoke twice before physicians' groups in Rochester.

At 11 A M Doctor White held a practitioners' clinic on heart diseases at Genesee

Hospital Luncheon was served after the clinic. Members of the Rochester Academy of Medicine heard Doctor White discuss "Cardiac Problems in General Practice" at the Academy in the evening.

New York County

DR. REGINALD M RAWLS, specialist in obstetrics and gynecology who was on the staff of the Woman's Hospital for thirty-five years, died of a heart attack on Dec 30 at the hospital. He was sixty-three.

DR JOSEPH E FULD, consulting surgeon at City Hospital, on Welfare Island and a specialist on hand injuries, died on Jan 3 at his home, 125 East Eighty-fourth Street. Dr Fuld, who was sixty-four, was stricken with a heart attack.

In 1926 Dr Fuld reported in *The Journal of the American Medical Association* a successful operation in which he transplanted a toe to replace a finger.

One-third of the middle finger of a man had been cut off while he was working a bread-slicing machine. Dr Fuld was called promptly enough to find a favorable opportunity for transplantation. The little toe of the right foot was chosen as the member to be substituted. The operation was termed by Dr Fuld as valuable not only in giving a more sightly hand but in giving those whose occupation requires exceptional use of the fingers an opportunity to continue their work.

DR CAROLINE F FINLEY, a trustee of the New York Infirmary for Women and Children, which she had served for many years as an active member of the medical staff, died after a brief illness of heart disease, on Dec 28.

In 1918, Dr Finley became one of the first three American women to receive commissions in the French Army and was decorated with the Croix de Guerre for her work as head of an advanced hospital unit and as an operating surgeon. The citation of the French Service de Sante read:

"Dr Finley, head of the American Surgical Mission located at d'Ognon, a woman remarkable for her sterling moral and professional qualities, has rendered the greatest services to the French and American wounded. She is distinguished with all her staff for her courage and scorn of danger during the bombardment of the hospital by enemy aviators."

The aid rendered by Dr Finley to British soldiers at Metz who had been released from German prison camps in 1918 was rewarded

The purified air is protected from contamination by placing sterilized screens at the entrance and by thoroughly sterilizing the garments of both doctor and patient. The instruments which have been sterilized by steam are placed in the room to be purified again and at the same time the air is going through the process.

Prof Gudin has substituted chemical for steam sterilization with the following advantages: there is perfect sterilization, material does not deteriorate, the process is more rapid and involves a minimum of labor and it is possible to sterilize such objects as the x-ray machine, electric light fixtures, and instruments for applying anesthetics.

The operating room is composed of two floors and is completely isolated by means of sterilized screens. The surgeon enters unclothed and in an ante-chamber dresses himself in sterile garments. The patient likewise undergoes a completely purifying treatment and is placed on a movable table which is then wheeled into the operating room proper. Fewer attendants are re-

quired since all objects in the room are germ-free.

The students and observers may watch the proceedings from the second floor and are thus able to obtain an unobstructed view. Since they are isolated, there is no danger that they may be contaminating the atmosphere. Lights placed directly in front of the surgeon and his attendants provide sufficient illumination to make all motions clearly visible.

Prof Gudin maintains that if this procedure is closely followed wounds will close without becoming red or inflamed, and will heal without leaving any scar at all. He has proved the efficacy of this new technique by many experiments, and in conclusion states, "Complete sterilization is a precise, scientific weapon in combating post-surgical infection."

"At first glance it may appear contrary to our present practice, but actually it is the full realization of the ideals conceived by Pasteur."

Hospital Congress in Paris in July

THE FIFTH INTERNATIONAL CONGRESS OF HOSPITALS will be held in Paris, France, on July 6-11. At the Congress in Rome, May 1935, the International Hospital Association decided to hold the 1937 sessions in Paris. Previous sessions had been held in Atlantic City, Vienna, and Knocke Sur Mer, Belgium. The meetings will occur during the International Exposition.

Dr. Malcolm T. MacEachern of the American College of Surgeons is vice-president of the International Hospital Association.

The meetings will include visits to some of the large hospitals, the Cancer Institute

and the principal agencies engaged in public health work. Scientific and pleasure tours will be conducted in various parts of France.

Persons attending the Congress will be granted important reductions in rates when traveling on French and foreign railroads. The Exposition authorities also will give special privileges to visitors.

The Chairman of the Committee on Arrangements for the Congress is M. Albert Chenevier, secretary-general of the Department of Public Assistance in Paris. Further information may be obtained from M. Chenevier, No. 3 Avenue Victoria, Paris IV, France.

Millions for New Hospital Projects

THE 1937 CAPITAL BUDGET submitted by Hospital Commissioner Goldwater calls for an expenditure of \$60,503,797 by the city of New York. Among the thirty-seven hospital projects is included erection of the following new buildings:

A 500-bed tuberculosis hospital in Queens near the Triborough Bridge, a tuberculosis hospital in the Bronx, for Brooklyn, a venereal diseases hospital, a contagious diseases hospital for the Bronx, a new 500-bed hospital for Harlem, and a 600-bed

hospital for the Brownsville-East New York section of Brooklyn. Construction of a consolidated dispensary for the hospitals on Welfare Island is the most urgent need.

Second in importance, building a convalescent day camp on the site of the old Welfare Island work-house. Also included are additional elevators to link the Queensboro Bridge with Welfare Island, added facilities at Riverside Hospital, a 300-bed psychopathic pavilion for Kings County Hospital, a new administration building for

Hospital News

Bellevue Opens New Laboratory For Tropical Diseases

A NEW LABORATORY FOR sub-tropical and tropical diseases has been opened at Bellevue Hospital, Dr S S Goldwater, Commissioner of Hospitals, announces

A three years' survey at Bellevue has shown that various tropical and sub-tropical diseases, parasitic infestations in particular, are common among the foreign population of New York City. They often remain undiagnosed because of lack of proper laboratory facilities. Many of the conditions are curable. In some instances, such as in hook-worm disease and trichinosis, small epidemics may be forestalled or controlled.

The new laboratory will be under the immediate supervision of Dr Douglas Symmers, General Director of Laboratories of the Department of Hospitals, and will be the immediate charge of Dr Harry Most of the New York University Medical College and Dr Amanda Hoff of Columbia University, both graduates of the London School of Tropical Medicine. The services

of this laboratory will be available to hospitals throughout the Department.

The laboratory has agreed to participate in the nation-wide survey of the United States Public Health Service to determine the incidence of trichinae in man, that is to say, the pork roundworm which causes the disease known as trichinosis and which follows the eating of improperly cooked pork infested by the worm.

The laboratory is prepared to study peculiar forms of malaria, including the cerebral variety encountered among the insane, the mental symptoms of which are curable if the cause is discovered in time, the occurrence of hook-worm, especially among Porto Ricans residing in New York City, various other intestinal parasites, obscure forms of leprosy, yaws, sprue, Delhi boil, Madura foot, Bilharzia and related fluke diseases, beri-beri, the Peruvian wart disease, both amoebic and bacillary dysentery, and trachoma.

Sterilizing an Entire Operating Room

PROF M GUDIN, of the faculty of surgery of Rio de Janeiro and a member of the Academy of Surgery in Paris, believes in going the whole distance when it comes to aseptic surgery. *Health Digest* abstracts an article from *Sintesis* (Mexico City) telling of some of his radical methods. After twenty-five years of following accepted aseptic practice, he is quoted as saying, "I reached the firm conviction that in spite of all precautions, it was impossible to avoid gaseous gangrene. Although doctors rigorously observed aseptic treatment, I have seen unfortunate cases resulting from the removal of even one stitch. Patients suffered from infections in the wounds, from meningitis, blood poisoning, or peritonitis, which frequently caused death."

In his long experience, Prof Gudín believes that the solution to the problem lies in absolute sterilization, carrying it to the extent of purifying the air to avoid contamination. The present system is very de-

ficient. Operations are performed with rubber gloves, bandages, instruments and thread that have been contaminated by exposure to septic air on flesh equally contaminated.

Air is a permanent cause of infection in operations. There are germs in the air and more are brought into the operating room by people, vehicles, and instruments.

In combating infection by air, operating rooms have been built with smooth walls, tile floors, and rounded corners to enable thorough cleaning. Even these precautions are insufficient. Infection can be avoided only when the operation is performed in an absolutely sterile atmosphere.

To attain this objective, Prof Gudín uses a machine manipulated by remote control. It is placed in an hermetically sealed room to neutralize toxic elements by means of specially treated ammonia. For the removal of all impurities, the air is passed through a solution of tartaric acid and sterilized water.

nounced Last year, Doctor Swan said, twenty-three ten year cures, out of forty-three reported as five year cures in 1930, were reported This year he was able to report twenty-one ten year cures out of thirty-five reported as five-year cures in 1931

Dr Thomas Jameson of Highland Hospital reported a twenty-eight year cure for one patient on whom he operated for stomach cancer in 1908.

NIGHT OPERATIONS ARE DANGEROUS, declares the *Modern Hospital* It is strongly suspected if a careful examination of morbidity and mortality statistics covering the so-called emergency operations performed from dark to dawn could be made that these percentages would be startlingly high

Inherent in night surgery are several factors peculiar to this time and type alone There is the emergency nature of the ailment, often present, just as frequently absent. The fatigue of the operator and his assisting staff, the real or imagined lack of time for a thorough study of the patient and the spirit of hurry, often unnecessary, all tend to breaks in technique and the exercise of faulty judgment Moreover, night is the only time when exacting surgical chiefs permit assistants to perform any solo work Herein lies at least one explanation for the frequency of night surgery

This factor represents an added danger to the patient Errors of diagnosis, disaster from infection and hemorrhage or any other unfavorable occurrence which befalls the night surgical patient just as much incriminate the chief surgeon as if he himself performed the operation A glance at the pathologists report on specimens removed from such patients will reveal to the hospital executive the truth as to the presence or absence of an emergency which required immediate surgical intervention

The less frequent the night laparotomy the better will it be for the patient and the hospital

THE PRESBYTERIAN HOSPITAL of New York has begun the construction of a convalescent home at an estimated cost of \$155,000 on its King Street property opposite Glenville Road in Port Chester The Presbyterian Hospital and Columbia University sponsor an experimental station on the property, working with sheep and other domestic animals

Bellevue, and a new nurses' home for the same institution

Plans call for a new out-patient building for Kings County Hospital, substantial additions to Cumberland Hospital, a pavilion for contagious diseases at Queens General Hospital, new buildings for Sea View Hospital, permanent buildings at the Farm Colony, where 400 inmates are now housed in shacks, a new home for dependents on Welfare Island to replace the present antiquated structures, a new cancer hospital building on

Welfare Island, new quarters for the chronic disease hospital on welfare Island, and a tuberculosis pavilion at Kings County Hospital

Also, additional buildings and an out-patient clinic at Coney Island Hospital, a new out-patient building for Harlem Hospital, and a 100-bed increase in the capacity of the Municipal Sanitarium at Otisville.

This program was passed on by the Hospital Council of the City of New York at its meeting of December 15

Diseases Under Study at Rockefeller Institute

THE HOSPITAL OF THE Rockefeller Institute for Medical Research, at 66th St. and York Ave., New York City, is investigating certain diseases, and accepts selected cases that bear upon the subjects chosen for investigation. Suitable patients may be referred to the hospital by physicians willing to cooperate. No charges are made for treatment, room, board, or any other services. Physicians are asked to telephone (REgent 4-8000) or apply personally to the Resident Physician before sending patients. An ambulance will be sent if necessary. The following diseases are now under investigation:

I Blood Diseases—Aplastic, idiopathic pernicious, or severe microcytic anemia, sprue,

or severe glossitis and stomatitis without anemia.

II Nephritis—Nephritis in initial acute stages, nephrosis, arteriosclerotic nephritis, in both adults and young children.

III Heart Disease—Advanced heart failure in all age groups, but especially in older patients.

IV Rheumatic Fever—Any early acute form, arthritic or visceral, also acute sore throat and hemolytic streptococcal infections in rheumatic subjects.

V Chicken-Pox, Measles—Measles in pre-eruptive stage, chicken pox, encephalitis following measles, vaccinia, chicken pox, whooping cough or common cold.

VI Acute Respiratory Diseases—Acute lobar pneumonia and acute broncho-pneumonia in adults, both preferably in early stages. An oxygen chamber is available for suitable patients. Influenza in early stages.

Hospital Notes

HOSPITAL INSURANCE FOR WESTERN NEW YORK—The Hospital Service Corporation of Western New York went into operation Jan. 1, with headquarters in Buffalo. Carl M. Metzger is the executive director. The plan, which offers twenty-one days of hospital care, exclusive of physicians' fees, has been approved by the Medical Society of the County of Erie. The charter provides for service for Erie, Niagara, and Chautauqua counties. Eight hospitals in Buffalo, one in Lackawanna, and two in Niagara Falls are participating, each represented on the board of directors. The medical societies concerned are also represented on the board.

THIRTY-ONE NEW five-year cures of cancer, bringing the total to more than two hundred recorded by Rochester hospitals, were reported to the New York State Committee of the American Society for the Control of Cancer, meeting for a scientific session in Genesee Hospital, on Dec. 8.

Dr. John M. Swan, executive secretary, reported comparative statistics which showed early diagnosis and treatment in Rochester hospitals by local physicians has brought relief without recurrence to many patients over five and ten year periods.

Forty-four cures without recurrence over a ten year period are now on record in Rochester hospitals, Doctor Swan an-

al fees occurs between a physician and a layman, or a physician and a physician in cases prohibited by the canons of ethics, or, as is the situation here, between a physician and a hospital. In the latter case an outside agency participates financially in the compensation of the physician licensed by the State to practice medicine. Inevitably such a method of division would lead to deterioration in the medical staffs of hospitals with attendant injury to the public. It would likewise subject some physicians to the temptation of overcharging their patients in order to meet the requirements of the hospital rule.

It is conceded even by the Salvation Army, the alternative beneficiary, which would take in the event that the disputed gifts were ineffectual, that no reputable hospital in the United States has applied the rule of division of fees or compulsory charity sought to be enforced by the testator in his will.

In the case of one of the hospitals which is a beneficiary here, it has been established that two hundred and eighty physicians and surgeons give their services free for the treatment of indigent patients. At the same time most of them use the facilities of the hospital for treatments of or operations upon patients who can afford to pay. The revenue derived from the renting of the rooms, operating rooms and other facilities enables the institution to support, to a large extent, its charitable activities in the treatment of free patients in dispensaries or in the hospital wards.

It is argued that serious difficulty would arise in the ascertainment, under the terms of the will, of the compensation received by the physician from paying patients for the services rendered in the hospital and those rendered before or after hospital treatment. It is urged that it would be impossible to properly allocate these charges so as to compute the basis upon which the ten per cent is to be determined. Certainly there would be a practical difficulty in this process. Ordinarily the difficulty in enforcing a condition might not be a ground for a determination of invalidity, but where, as here, it is mingled with a requirement that is unreasonable, unethical, and in violation of public policy, the court cannot sustain it.

The situation here finds a parallel in an assumed case, where there might be a legacy or trust to a bar association upon condition that any attorney using its library or conference rooms would pay to such bar association a percentage of his compensation derived from his client in whose interest he uses its facilities. That condition in the will would not only be almost impossible of enforcement in the allocation of the actual amount of compensation derived from the time spent in the association, but would involve the unethical and improper division of the attorney's professional fees. No one would dispute, with any pretense of logic or ethics, the invalidity of such a provision as applied to an attorney. Similarly the attempt of the testator here to fasten a new custom upon the medical profession is equally obnoxious and contrary to the best interests of the community.

The charitable purpose of the testator is obvious and his intention to benefit the hospitals which he selected clear. The difficulty, however, is that he attempted to impose a rule of compulsory charitable contributions upon others. The method which he devised to compel physicians to be charitable is bad and not entitled to legal recognition."

Diathermy Burn

A young man consulted a general practitioner with respect to complaints of pain in his lower back which radiated down the left thigh and leg. The doctor could find no objective evidence of injury and advised diathermy treatment. The doctor administered a twenty minute treatment setting up the machine so that one tin-foil electrode was under his right thigh as he sat in a chair. The other tin-foil electrode was placed on the wooden floor under his bare foot. A series of such treatments were given to the patient without any untoward happening and finally when the patient was undergoing such a treatment, and the electrodes had been in position for about five minutes the patient suddenly jumped from the chair and moving to one side, saying he had been burned. The doctor found that there was a burn on his thigh at the point where the electrode was attached. Examination showed that the injury had been caused by the rubber covering over the copper wire burning off from the copper wire which ran from the machine to the electrode. Before the treatment the doctor had looked at the said wire and it apparently had been in good order. The burn was about the size of a silver dollar and the doctor treated it from time to time for about three weeks, at the end of which time the burn had healed.

An action was brought against the doctor, charging him with having negligently caused the plaintiff to sustain a burn. An investigation of the matter revealed that the patient had made a claim for workmen's compensation with respect to the original condition for which he consulted the defendant. An award was finally made to him covering a period of disability which took in the time during which the defendant had administered all of the diathermy treatments and the time during which the burn had been treated.

Under the circumstances the facts of the compensation award was pleaded as a defense in the action. The case came on for trial before a judge without a jury and at the close of all the testimony the judge directed a verdict in favor of the defendant.

LORENZ J. BROSNAN, ESQ

Counsel, Medical Society of the State of New York

Wills—Conditional Bequest to Hospital

A case* recently arose before the Surrogate's Court of New York County in which the question at issue was the validity of a certain condition attached to a gift made in a testator's will to certain hospitals. The decision handed down by the Court was one which should be of general interest to members of the medical profession.

Among the provisions of the Testator's will was a clause setting up a trust of \$200,000 in favor of the sister of the decedent. The will directed that the income from said sum was to be paid to the sister for life and until the time of her death it was in fact so paid. However, the will further provided that upon the death of the testator's sister the trustee should divide the trust fund into seven parts and pay over the income to certain designated charitable corporations. Two of those institutions named in the will were hospitals maintained as charitable institutions in the City of New York. The will specified that the gift to each of those hospitals was upon the following terms and conditions:

That each such institution (in case it shall be one in which physicians shall practice at any time) shall make a binding rule to the effect that any and all physicians at any time practicing for remuneration in the said respective institutions shall be required to and shall pay toward the maintenance and support of the said institution a sum of money equal to ten per cent of the gross fees which shall at any time be received by such physicians respectively for services performed by them in the said institutions. In the event that any one of the said institutions shall refuse to make such a binding rule or after having made such a binding rule shall thereafter abrogate the same or neglect to enforce it, then and in that event the trust so created shall cease to operate and the capital of the trust created for the benefit of such institution shall thereupon be turned over by my said Trustee to the Salvation Army. My said Trustee, however, shall be thoroughly protected as regards any payment made to any one of the said seven institutions until such time as it shall have actual knowledge that any one or more of the said seven institutions is not enforcing the rule above set forth, covering the contribution by physicians

The effect of the condition imposed upon the gifts to the hospitals was that those institutions would have been under the will required to establish a rule that all physicians practicing within those institutions should be required to pay to the respective hospital ten per cent of the gross fees received by the doctors in connection with services performed by them in the hospital.

Upon an accounting proceeding, the question of the validity of the conditions referred to was challenged by the hospitals. It was contended that the conditions specified in the will would require them to operate their hospitals in a manner contrary to public policy since the requirement would compel the division of fees by physicians in the manner commonly called "fee splitting" in violation of the canons of ethics in the medical profession. The hospitals also contended before the Surrogate that the rule contemplated by the testator would be unreasonable and impossible to enforce and that it would probably result in the resignation from the staffs of the hospital of various eminent physicians who would not care to participate in any such arrangement.

There was the further argument that if such an arrangement were imposed upon the physicians practicing at the hospitals they would in order to regain their losses impose upon their patients unnecessarily large fees.

Mr. Surrogate Foley, before whom the proceeding was heard, held that the conditions attached to the gifts to the hospitals were void and that the gifts were valid gifts to the said institutions free from the conditions which the testator sought to impose. In so ruling Surrogate Foley in the course of a well-written opinion stated in part:

In my opinion these contentions are correct and the condition sought to be imposed by the testator is contrary to public policy, unreasonable, impossible of performance, and void. I hold likewise that the condition may be stricken from the will and that the income may be paid to the two institutions that the trustee free from any conditions by the trustee free from

It is immaterial whether the division of med-

Escape

OUR BOASTED CIVILIZATION has now reached such a pinnacle of perfection that thousands are trying to escape from it. Escape—that is the word that is being used more and more to explain our behavior. It is used to explain why we burn up gasoline at sixty miles an hour, tearing through rural scenery to consume an indifferent dinner at some late hour, far, far from home. That, we are told, is what explains it. It is far from home. Escape! The weak man fortifies his soul with artificial stimulation and escapes from his inferiority complex. With a high-powered car under his hand, he becomes a king, or, higher yet, a fuhrer, a duce, until he meets another similarly exalted dictator, and both may escape from the world and its worries entirely, in a crash of rending and writhing steel.

The soothing influence of Lady Nicotine permits us to forget our troubles and beatifically build the air-castles of our dreams in the soft, grey clouds of billowing smoke, but the huge police bonfires of tons of marijuana weed, otherwise known as hemp or bhang, testify to the fevered desire of other misguided souls to escape even further—into purple realms of half-insanity where everything wrong is right, all inhibitions are repealed, and a satonic paradise is realized.

Even the familiar household radio, we are assured, takes us out of our humdrum lives into spheres of music, humor, and other forms of entertainment, and is really a vehicle of escape. The widespread, almost universal, desire to get away from ourselves is seen in the fact that we are surrounded with these escape mechanisms. No previous era in the history of the world has ever seen anything like it. We seem to be in a mad scramble to elude reality. How happy our civilization must be when so many of its improvements are designed to make us forget it.

Movies Lift Us into Other Worlds

Perhaps the most potent escape mechanism of them all is the movie. The spectator

identifies himself or herself with the character on the screen and lives in the romance or intrigue played out in the flickering lights. What a disagreeable jolt it must be when the play ends, husband and wife turn and look at each other, he realizes that she is no Mae West, and she realizes that he is no Gary Cooper. Back they must go to the drab routine of actuality until another chance to escape. That this is no mere fancy was shown by the wave of feminine suicides following the death of Rudolph Valentino. Their dream-partner was gone, and they could not endure a world without him. One way of escape was cut off, so they took another.

What makes the mischief is the fact that the fugitive from reality finally is happy only when he is in his other-world. He becomes out of adjustment with real life. His home, his family, his work, are things to escape, to evade. He grows unstable, incompetent in ordinary matters, lazy and useless. He or she drifts into physical or mental ill-health, and cure or relief is often difficult.

Have We Grown Softer?

Certainly no one can say that our civilization is duller or less interesting than that of a hundred years ago. We have a thousand interests that were unknown to our grandfathers—why, then, do we grow so tired of it all that we must escape from it at any cost? Is it possible that we may find the answer by looking within ourselves? Have we grown softer? The Americans of earlier days had a hard, ironbound philosophy of life that we do not care for, it may be, but at least they expected their existence to be full of difficulties, they believed that "man is born to trouble as the sparks fly upward," so they met life like men and women, without trying to evade or elude it, and that is one reason why we have our magnificent America of today. In many and many a town in this Empire State are spots where the men defended their log cabins from yelling, painted savages while their women loaded the muskets and passed them to

Alleged Failure to Deliver Placenta Intact

A doctor, who in the course of his practice handled a considerable number of obstetrical cases, was consulted by a woman in her early thirties who was about three months pregnant, and she requested him to assume the care of her. The doctor had treated the same woman previously for various conditions including endocervicitis and endometritis. The doctor saw the patient approximately once a month and in due course she entered a hospital and was delivered by him of a healthy living child. The delivery was a normal easy one, with the placenta delivered intact. The convalescence of the patient at the hospital was uneventful except for a few minor complaints of pain in the legs. She was discharged twelve days after delivery. The doctor never cared for the patient after that date.

It was later learned by the doctor that about two months after she left the hospital she had entered a sanitarium and had undergone an operation under a diagnosis of retained secundines. It was the opinion of the physician that the case was one in which the complications had been caused by a succussory placenta.

The patient and her husband brought a malpractice action against the doctor in which the charge was made that the defendant had negligently failed to remove the entire afterbirth.

When the case came on for trial it was assigned in its order for trial, and just as the jury was about to be chosen, plaintiff's attorney made an application for an adjournment making the claim that he had been unable to subpoena an important medical witness. The court, however, denied the application and when the plaintiff failed to proceed with the trial without the witness, the action was dismissed.

Treatment of Cyst

A fifteen year old girl was brought by her mother to the office of a general practitioner with complaints of a painful condition about the left ear. The doctor found she had a cyst of about three weeks duration, but she had no fever. He cut off her hair about the cyst and painted the area with tincture of iodine and then under a novocain anesthetic he incised around the cyst and removed it completely. He found no pus, and deciding there was no need for a drain, he sutured the edges together and applied a dry dressing. The patient returned every second day and the wound was re-dressed until on the fourth visit the doctor found signs of infection. He removed the sutures and pus was emitted. On that occasion the wound was left open and re-dressed, and the patient's condition went on satisfactorily for about ten days further when in response to a call the doctor went to the patient's home where he found the girl in bed with a temperature of 101°F. Again the wound was reopened, a drain was inserted, and a dressing was applied.

The next day the doctor received word that another physician had been called to take over the case, so he never saw the girl again.

A malpractice action was brought on behalf of the girl against the doctor in which the complaint specified that the defendant had failed to diagnose and treat properly a mastoid condition. A notice of trial was served by the plaintiff's attorney but he never filed the necessary papers to place the case on the calendar of the court, and in due time the case was disposed of by an order of dismissal granted by reason of the failure of the plaintiff to diligently prosecute the case.

MEETING FOR CARDIAC STUDY

A meeting of the New York Heart Association (Heart Committee of the New York Tuberculosis and Health Association) will be held at the New York Academy of Medicine, Room 550, on February 9 at 8 30 P. M., with Dr. Ernst P. Boas, Chairman of the New York Heart Association, presiding. The meeting is open to all physicians.

Following the presentation of a paper on "Clinic Studies of Venous Pressure" by Dr. John L. Caughey, Jr., discussion will be

opened by Dr. Arthur M. Fishberg. Two papers will be offered on "The Effect of the Xanthines on the Coronary Circulation," Dr. Nathaniel T. Kwit presenting "The Xanthines in the Treatment of Cardiac Pain," and Dr. Janet Travell "Theophylline in Experimental Myocardial Infraction." Discussion of these papers will be opened by Dr. Arthur C. DeGraff.

At this time the Annual Meeting of the New York Heart Association will also be held.

for active service. President-Elect Edmund D. Clark of our association urged this point.

Unfortunately, we are told, doctor's wives often shun such committee work on the grounds that it is not fitting for them to be thus active, nevertheless, it is a well-known fact that among the members of your clubs are the wives of hostile nonmedical practitioners who seek membership on such committees and who, therefore, exert a strong influence in favor of legislation hostile to the medical profession.

Another rather intriguing idea advanced by Dr. Emerson is "that you cordially invite to your meetings the wives of the many excellent physicians who have not joined the Indiana State Medical Association. You may by this method be the indirect means of converting the latter. We need them."

Wisconsin's Example

On the splendid work of informing the public on health matters our auxiliaries are already launched. Dr. Emerson, in speaking on this point, told of the excellent program of the Wisconsin Auxiliary.

The great need of the public is education in the truth concerning the cure, control, and prevention of disease. In this field the auxiliary can prove most helpful. By teaching the public the value of excellent medicine they can do far more to defeat hostile legislation than by any direct political action.

The public never seems to realize, because they are so often told otherwise, that the members of the State Medical Association ask nothing which benefits them directly or indirectly, on the contrary, that which doctors so insistently demand always tends to eliminate disease and, therefore, to lessen medical practice. This educational problem may be approached in various useful ways.

The Wisconsin Auxiliary, I am told, organizes classes among its own members who study various aspects of social medicine, mental hygiene, the problems of state medicine, poor relief, etc., and that later its local branches, working under the direction of the proper committee of the State Association, organize and sponsor public meetings, demonstrations, exhibits, for community education in these subjects, also, that they maintain a bureau through which lay organizations may obtain suitable speakers for their meetings.

THE PASSING OF "CHOLERA INFANTUM"

A chill of terror used to strike the hearts of mothers at the very words "cholera infantum" during the first year of their babies' lives. Each summer, as the *Bulletin* of the New York City Health Department recalls, saw thousands of these little victims die and there seemed no way of conquering the scourge. Medical science had

looked upon the disease as a specific entity, in fact after the remarkable bacteriological discoveries during the eighties, laboratory workers sought to discover the specific causative agent. To Park and Holt goes the credit for demonstrating conclusively that there is no specific germ of "cholera infantum," but that diarrhoeal disease in infants is largely due to milk containing an excessive number of ordinary dirt bacteria. With this fact as a basis the control of summer diarrhoea resolved itself largely into an effort to provide a safe and clean milk supply.

Some idea of the role played in infant mortality by summer diarrhea may be gained from a study of the graph showing the average annual infant deaths in New York City, by weeks, in 1898-1900 and in 1931-35.

The graph shows clearly how, until about ten or fifteen years ago, the number of infant deaths rose sharply each summer.

The rise during the summer has become progressively less marked until now the infant mortality is invariably lower in summer than at any other time.

the fighters without a tremor of cowardice. They expected life to be like that. But now we are bored, ennuied. Life is not amusing enough, so we must escape from it.

The folks who figure up the health statistics find that more and more people die because their hearts fail. We might say that they haven't the heart to live. So one of the tasks of the medical men now is to find a way to strengthen our hearts,

and make them stand up to their work better, and longer. The heart, the *cour*, used to be thought the seat of courage, and perhaps what we need, along with stronger hearts to meet our physical trials, is a better outfit of the plain, old-fashioned courage, the grit, yes, let's say it, the "guts" that carried the men and women of those days through scenes of blood and fire that we never know.

The Auxiliaries Mean Business

ANY FOLKS WHO THINK that the Women's Auxiliaries of the County Medical Societies now forming rapidly all around the State are organizing merely for social and recreational purposes are going to find themselves vastly mistaken. True, they are having their bridge and theater parties, where they will come to know each other better, but the reports of their meetings show that they are listening to speakers on serious medical and health topics, and are preparing to aid the campaigns of the county societies in their eternal warfare with disease.

Take an item in the Syracuse papers of January 3. "Arrangements have been completed," it ran, "for the opening dinner and mass meeting of the lay educational portion of the maternal welfare campaign." Who had charge of all the arrangements for the dinner? The Women's Auxiliary of the Onondaga Medical Society. And what is more, we are informed, the Auxiliary is also making arrangements with the various lay organizations of the county for speaking engagements, by which physicians of the county society will appear before social and service clubs to explain the objectives of the maternal welfare campaign and tell how each one can help. And this is only one county. The other auxiliaries are also busy along similar lines.

A few weeks ago the state Auxiliary of Indiana asked a leading member of the State Medical Society, Dr. Charles P. Emerson, of Indianapolis, to address them on the topic "What Can the Women's Auxiliary Contribute to the Practice of Medicine?" At the rate that our own auxiliaries are going, perhaps Indiana will be able to learn something from New York, but, in the meantime, it may be of interest to listen to

the voice of Indiana, and, if advisable, to take a leaf from their book.

A Wide Field of Influence Open

One suggestion made by Dr. Emerson was given to him by the President-Elect of their State Medical Society, so it has double backing. It is that the members of the Auxiliary use their influence in helpful ways, not alone in the Auxiliary, but in the other clubs, societies, and organizations where they may happen to belong. Serious questions are now up that affect the medical profession, sinister influences and movements threaten, it is an hour of crisis, and to sway these clubs and societies to the right side would help mightily. Dr. Emerson's words are worth quoting.

Medical politics is one of the most dangerous of the avocations of physicians, yet since we Americans live in a society the fundamental organization of which is political, our profession cannot escape. State medicine is threatening us, hostile medical cults are trying through political means to exploit the already prejudiced public, and only in the political arena can both dangers be averted.

Medical auxiliaries as such should not directly engage in any political activity, since they cannot present the medical side with authority. There are, however, ways in which the auxiliary can be of great assistance politically.

Practically all of you belong to some other organizations or clubs which have legislative committees. In your own fields you can speak with authority. Some of you are graduate nurses, others are trained social workers. Both groups have nation-wide organizations.

The majority of you belong to federated women's clubs and parent-teacher associations. These always exert a powerful influence over legislation. On the proper committees of these clubs the wives of physicians might well enlist

Theory and Practice of Psychiatry By William S Sadler, M D Quarto of 1231 pages St. Louis, The C V Mosby Company, 1936 Cloth, \$10.00

This is a large volume of 1231 pages in which much of the subject matter deals with the non-institution types of mental disease, the kind one treats in the office. The book is, therefore, quite different from the regulation type of textbook on psychiatry. The conviction is expressed "that the mental hygiene problem will never be adequately solved—unless the entire medical profession awakens to an interest in the increasing army of those who are afflicted with neuroticism, emotional disturbances, personality disorders and the more serious psychoses." An appeal is addressed to the psychiatric and other specialists and the general practitioner to be ever mindful of the need to practice mental hygiene. The author expresses the opinion, which is shared by many psychiatrists, that the practice of mental hygiene could be advantageously broadened.

The author seems to be neither a radical nor an ultra conservative but is rather an exponent of the "American School of Psychiatry," the so-called "middle-of-the-roads."

In part I, among other matters, are discussed psychological principles, mechanisms, symptoms, and the examination of the patient, in part II there is a lengthy discussion of personality development through the different age groups, part III takes up the neuroses at some length, over 300 pages, part IV considers the psychoses, 130 pages, part V is given over to the subject of psychotherapeutics, about 230 pages.

This book will not please every reader but there should be help in it for every physician and others interested in the welfare of nervous and mental patients. It is different from most other books on the subject of mental disease in that much space is given to a study of the patient as a whole, with his various reactions and personality deviations and suggested lines of treatment.

In the back of the book is a helpful dictionary of terms and, everything considered, it should be a helpful addition to any psychiatric library.

A. E. SOPER

Passive Vascular Exercises and the Conservative Management of Obliterative Arterial Diseases of the Extremities By Louis G Herrmann, M D Octavo of 288 pages, illustrated. Philadelphia, J B Lippincott Company, 1936 Cloth, \$4.00

With the recent increasing interest in diseases of peripheral blood vessels, a

monograph reviewing the widely growing literature on this subject is a welcome addition to the physician's library.

The book contains an excellent historical review of work done with physical alterations in environmental pressure. One notes progressive mechanical improvements in time, and Herrmann's work consists of the perfection of a mechanical device which automatically alternates these environmental pressures.

The author's first experimental report showed the beneficial effects of using intermittent periods of negative pressure alone. Simultaneously with the author's early report, there appeared the work of Landis and Gibbon with the use of both suction and pressure. The book contains a detailed description of the work from both schools and appears to be intended to establish the author's priority.

Herrmann had observed undesirable effects from positive pressure, and felt that this phase of treatment was associated with such dangers as spreading infection and the production of phlebitis. In his earliest report he seems to have discarded the phase of positive pressure for he is "convinced that true beneficial effects are obtained from the action of intermittent negative pressure" (quoting author). The reviewer is unable to understand why the positive phase was again introduced.

The book does not contain sufficient photographs of conditions before and after treatment, commensurate with the extent of the author's experience. Although he attempts to present a convincing argument for the value of this mechanical method of treatment, its evaluation will have to await further studies both by the author and workers in other clinics. So far, publications appearing from other groups have not been as enthusiastic as the author's.

Any one desirous of being posted on the latest developments in the treatment of peripheral vascular disease must read this book.

WILLIAM S COLLENS

The Study of Anatomy Written for the Medical Student. By S E Whitnall, M D Third edition Duodecimo of 113 pages Baltimore, William Wood and Company 1936 Cloth, \$1.75

This is the third edition of a small volume containing seven chapters which deal with the Nature of Anatomy, Practical Methods of Study, Books of Reference, Teachers and Lectures, Examinations, General Reading and Bibliography. The work is not a dissecting manual, nor does it discuss anatomy in the usual manner. It is a lecturer's

Books

Books for review should be sent directly to the Book Review Department at 1313 Bedford Avenue Brooklyn N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

RECEIVED

Cosmetic Dermatology With dictionary of ingredients, discussion of anatomic, physiologic, and pharmacologic bases of cosmetic application, "shelf-tested" formulae, and appendices on odor and color in cosmetics. By Herman Goodman, M.D. First edition. Octavo of 591 pages. New York, McGraw-Hill Book Company, 1936. Cloth, \$5.00.

Food and the Principles of Dietetics By Robert Hutchison, M.D. and V. H. Mottram, M.A. Eighth edition. Octavo of 634 pages, illustrated. Baltimore, William Wood & Company, 1936. Cloth, \$6.75.

Applied Dietetics The Planning and Teaching of Normal and Therapeutic Diets. By Frances Stern. Quarto of 263 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1936. Cloth, \$3.50.

Skin Diseases in Children. By George M. MacKee, M.D. & Anthony C. Cipollaro, M.D. Octavo of 345 pages, illustrated. New York, Paul B. Hoeber, Inc., 1936. Cloth, \$5.50.

Approaching Motherhood Questions and Answers of Maternity. By George L. Brodhead, M.D. Fourth Revised Edition. Duodecimo of 196 pages. New York, Paul B. Hoeber, Inc., 1936. Cloth, \$1.50.

The Principles of Bacteriology and Immunity By W. W. C. Topley, M.D. & G. S. Wilson, M.D. Second edition. Quarto of 1645 pages, illustrated. Baltimore, William Wood & Company, 1936. Cloth, \$12.00.

Surgery for Dental Students By Philip H. Mitchiner, M.D., Clement E. Shattock, M.D., Edward G. Slesinger, M.S. & Cecil P. G. Wakeley, D.Sc. Octavo of 364 pages, illustrated. Baltimore, William Wood & Company, 1936. Cloth, \$4.75.

A Synopsis of Surgical Anatomy By Alexander Lee McGregor, F.R.C.S. Third edition. Duodecimo of 664 pages, illustrated. Baltimore, William Wood and Company, 1936. Cloth, \$6.00.

Diseases of the Coronary Arteries and Cardiac Pain. Edited by Robert L. Levy, M.D. Octavo of 445 pages, illustrated. New York, The Macmillan Company, 1936. Cloth, \$6.00.

Oral Diagnosis and Treatment Planning. A Textbook for Students and D.D.S. Practitioners of Dentistry and Medicine. By Samuel C. Miller, Octavo of 620 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc., 1936. Cloth, \$7.50.

International Clinics A quarterly of illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, Neurology, etc. Edited by Louis Hamman, M.D. Volume 4, 46th Series, 1936. Octavo of 352 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1936. Cloth.

A Textbook of Medicine. By Charles P. Emerson, M.D. Quarto of 1296 pages. Philadelphia, J. B. Lippincott Company, 1936. Cloth, \$8.00.

REVIEWS

Bacteriology in Relation to Clinical Medicine Theoretical and Applied For Students, Laboratory Workers and Practitioners in Medicine and Public Health. By M. N. De, M.R.C.P. & K. D. Chatterjee, M.B. Quarto of 599 pages, illustrated. Calcutta, The "Statesman" Press, 1935. Cloth, 30/.

This text book differs from the standard American texts on bacteriology in the conciseness of presentation of facts, and in the profuseness and excellence of its illustrations. For the medical student and the physician with no special training in bacteriology it is sufficiently complete to make it a valuable book for study and reference.

The theoretical chapters are admirable in their clarity. The bearing of their significance to clinical problems is noted everywhere. The technical procedures are included in the sections dealing with various subjects and are precise in their details and easy to follow. There is no bibliography.

Several minor errors occur, which do not, however, detract from the value of the book. Among them is the reference to the pathology of rickets in its relation to tuberculous infection. The work of Abel on tetanus is no doubt too recent to have been included.

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W. 42nd St., N. Y. C.) postage prepaid. Order must be accompanied by remittance covering published price.

CLINICAL EVALUATION OF PROTAMINE INSULINHARRY G. JACOBI, M.D., *New York City**Associate Attending Physician, Lenox Hill Hospital*

In presenting observations on any new preparation, one must be careful to avoid unwarranted claims and inferences resulting from overenthusiasm. At the same time and by this very token, proper attention must be given to the matter of detail in order to insure a common standard of comparison of the results obtained by various investigators in the field.

We therefore feel that for the proper clinical evaluation of protamine insulin a thorough familiarity with the following essentials is necessary: (1) The actions and reactions resulting from the use of this preparation. (2) The indications and contraindications for its use. (3) The most practical method thus far evolved for calculating the dosage of the protamine insulin and the best time for its administration. (4) Other factors that may influence the blood sugar level and which may be erroneously interpreted as protamine insulin effect. (5) Whether protamine insulin after injection into the tissues, has a uniform rate of absorption and liberation and whether it has a cumulative action.

Origin of Protamine Insulin

As regards the history of protamine insulin, it may be briefly stated that it is the precipitate formed by the action of insulin hydrochloride with monopro-

amine compounds, and was first introduced by a group of Danish investigators¹ who were searching for a preparation which would give a more sustained lowering of the blood sugar than that obtained by the use of regular insulin. The protamine insulin resulting from this precipitation, after being properly buffered, was found to be relatively insoluble in tissue fluids, causing the insulin to be liberated slowly and over a prolonged period of time.

Further investigation showed that such substances as calcium and zinc had a tendency to increase this prolonged effect of the insulin action. Various combinations of protamine insulin with calcium and zinc were tried clinically in an attempt to see which had the most prolonged lowering effect on the blood sugar. The preparation which was finally decided upon is furnished as a five c.c. vial of protamine and insulin, prepared by mixing insulin containing protamine and zinc with a buffered solution in such a manner that each cubic centimeter, as supplied, contains forty units of insulin and approximately 0.08 mg. of zinc in combination with protamine in a precipitated form. The active material is present in the finely divided insoluble, white precipitate and not in the clear supernatant fluid. It is of the utmost importance, therefore, that an equal proportion of the precipitate be present in each dose injected.

Read at The Symposium on Protamine Insulin, Fourth Medical Division of Bellevue Hospital, December 15, 1936

attempt to make the study of anatomy interesting to the beginning student and to teachers of anatomy

It contains among other things the anonymous poem "To A Skeleton"

The author proves that there is something intensely interesting in the study of anatomy

HERBERT T WILKE

Methods of Tissue Culture in Vitro by Ralph Buchsbaum, Ph D, and **Outlines of Histological Methods with Special Reference to Tissue Culture** by Clayton G Loosli, Ph D Octavo of 81 pages, illustrated Chicago, University of Chicago Press 1936 Paper, \$1.00

In this pamphlet there is description of a simplified method of tissue culture Preparation of the laboratory room, the necessary glassware and instruments, media, and culture, and the simple technique are described in detail It should be of value to anyone interested in the culture of tissue

The second part of the pamphlet deals with the preparation of reagents and the technique of fixing the tissue, embedding it, sectioning, and staining

EDWARD H NIDISH

Neurological Surgery By Loyal Davis, M D Octavo of 429 pages, illustrated Philadelphia, Lea & Febiger 1936 Cloth, \$6.00

This is a well illustrated book dealing with disorders of the nervous systems that may be improved or cured by surgical therapy Injuries of the brain, spinal cord and peripheral nerves, tumors affecting the brain and spinal cord, infections implicating the central nervous system, the neuralgias and surgery of the autonomic nervous system are all discussed in a straightforward style Diagnosis and various methods of treatment, including not only surgery but also radio therapeutics, physiotherapy, etc, are presented Illustrative case histories are effectively used throughout This treatise, written for the general practitioner, is an attempt to emphasize just what may be accomplished in this particular field of surgery It is highly recommended as an accurate account of the present status of neurological surgery

JEFFERSON BROWDER

Microbiology and Pathology for Nurses By Charles F Carter, M D Octavo of 682 pages, illustrated St Louis, The C V Mosby Company, 1936 Cloth, \$3.00

This volume of 682 pages written for nurses covers bacteriology and pathology in such a dogmatic and elementary fashion

that it loses its purpose As an outline for review the book may prove of value to those who have been taught from some well accepted volume on the subject of bacteriology and pathology

While it is true that those for whom this volume was intended spend a very short time on both of these subjects during their training, it is also important that their source of information should be more comprehensive Otherwise an accumulation of factual knowledge may lead to a narrow point of view A good nurse is a valuable adjunct to medicine The sources of information accumulated during her student years should be comprehensive and not dogmatic In this respect this book fails of its purpose

MORRIS L RAKIETEN

The Riddle of Woman. A Study in the Social Psychology of Sex. By Dr Joseph Tenenbaum Octavo of 477 pages New York, Lee Furman, Inc, 1936 Cloth, \$3.50

In this comprehensive lecture Dr Tenenbaum examines woman as spinster, wife and widow, mother and mother-in-law, angel, gossip and criminal, prostitute and adulteress, witch and beauty The psychology, biology and social relations of woman are discussed in a calm, scholarly way It is interesting to note that the first woman physician to take a degree anywhere was Elizabeth Blackwell who was graduated from Geneva University (New York) in 1849

Strangely enough, the author is not a psychologist but a urologist practicing in New York City, who has already won recognition as an author Interesting and valuable and easy to read, the medical profession should appreciate this book.

CHARLES A GORDON

British Masters of Medicine. Edited by Sir D'Arcy Power, FRCS Octavo of 242 pages, illustrated, Baltimore, William Wood and Company, 1936 Cloth, \$3.00

This book is a compilation of brief biographical sketches of British masters of medicine, covering a period from Harvey, of the seventeenth century to Starling of the twentieth century The sketches originally appeared in the pages of the *Medical Press and Circular* They are elegantly written and cover the outstanding achievements of each of the prominent medical men who have contributed towards the progress of medicine Collectively, these short biographies delineate the evolution of science and medicine in Great Britain

WILLIAM RACHLIN

calculations that are made are in reality operable over a period of seventy-two hours. Changes in the dose of protamine are not reflected in the blood sugar or the morning urine, on the day the change is made. For this reason one must expect some glycosuria for the first few days after the commencement of the protamine insulin therapy.

There are several methods of procedure that have been followed by different groups of investigators in regard to the amount and time of administration of the protamine insulin. We have employed many of these, both in the same and different cases, and shall briefly mention them and illustrate their effect by means of case reports.

1 The method employed by the original investigators consists of giving a dose of regular insulin at 8 A.M. and protamine at 6 P.M. The A.M. dose of regular insulin is about twice that of the P.M. dose of protamine insulin. Blood sugar determinations are made at 7-11-2-5-10, the micro method of Folin¹ being used for this purpose. Daily qualitative tests for urine sugar are made at intervals of two to three hours from 6.30 A.M. to 9.30 P.M. and the ammonia content of the urine determined for the twenty-four hour period as an indication of fluctuations in the acidosis. The total amount of insulin used during the twenty-four hour period is increased or decreased as clinical and laboratory indications arise.

2. The reverse of the first method i.e., protamine insulin in the morning and regular insulin in the evening. The distribution of the carbohydrates in the three meals under this routine has been usually such that about one-fifth is given for breakfast, and two-fifths each for the other two meals.

3 The method of giving regular insulin before breakfast and supper and a dose of protamine at bed time (about 10 P.M.)

4 The method of giving both doses as protamine insulin, at a twelve hour interval, say at 8 A.M. and 8 P.M.

5 The method of using one dose of protamine insulin in the morning, supplemented by a dose of regular insulin administered at the same time but at a different site of injection. Various other modifications have been tried, too numerous to mention, and having no practical bearing on the subject.

Procedure

During our period of observation, we have used each of the above methods and

have found the following procedure to be most effective and practical. We allow a dosage of protamine insulin equivalent to about seventy per cent of the calculated regular insulin requirement that had been in use for the particular patient at the time. This is administered as one dose about one hour before breakfast. For the first four to seven days of this change, an additional dose of regular insulin equivalent to the remaining thirty per cent of the original insulin intake, is also given an hour before breakfast, using a separate syringe and a different site of injection. If after this four to seven day period, the morning urine fails to show sugar, the regular insulin is discontinued. If hypoglycemic reactions have occurred, the dose of the protamine is too large and should be reduced. If on the other hand, sugar continues to be present in the morning urine, either the dose of the protamine insulin is increased or the administration of the supplemental dose of regular insulin is continued. The rate of increase or decrease of protamine insulin is never more than five units at a time. We have found it advisable at intervals of four or five days, to do blood sugar determinations before each meal, in order to have a fairly good idea as to the glycemic response to the treatment. Urine specimens are collected daily—supper to breakfast, breakfast to lunch, and lunch to supper—and quantitative sugar determinations made. In this way a fairly good idea is obtained as to which part of the twenty-four hour period, is responsible for any glycosuria that may be present. It has been our experience that if the proper dose of protamine insulin cannot be arrived at to control the morning glycosuria, without precipitating hypoglycemic reactions, then the small supplemental dose of regular insulin should be given over a longer period of time instead of increasing the dose of the protamine. Emphasis is placed on the fact that this dose of regular insulin is made as a separate injection, otherwise it will be precipitated by the monoproamine and increase the effect of the protamine insulin.

Factors Influencing Blood Sugar Level

In all cases that fail to respond favor-

Protamine Insulin Action and Indications for Its Use

When a dose of protamine insulin, equivalent to a diabetic's usual insulin requirement, is injected into such a patient, no effect is noted until four to six hours have elapsed. If food is withheld, hypoglycemia will set in at about the ninth hour and this state will continue up to about the thirty-ninth hour, producing usually the train of symptoms either of those associated with hypoglycemia or those associated with acidosis and impending coma. It stands to reason that any preparation having such a marked and prolonged effect, can produce a great deal of trouble if not properly administered. Likewise its use can be greatly discredited by its injudicious employment.

What the medical practitioner is anxious to learn is the exact type of case or cases where this preparation may be of greater benefit than the regular insulin. From our experience and from the reports²⁻⁶ that have appeared in the short period of time, one gets the impression that the protamine insulin, if used wisely, may eventually prove to be a great advancement in the treatment of diabetes. On the other hand, its use without care or definite knowledge of its action, may produce harmful results and discredit the useful purpose for which it was intended.

As far as our experience permits us to judge at the present time, any case of diabetes which, in spite of proper diet and adequate doses of regular insulin, shows marked fluctuations in the blood sugar with or without episodes of hypoglycemic reactions, constitutes an ideal indication for the use of the protamine insulin. After considerable skill is obtained in the use of this preparation, this group of selective cases may be enlarged to include the average case of diabetes requiring insulin, where it is desired to obtain a more even blood sugar level during the twenty-four hour period, or where it is desired to diminish the amount of insulin, the frequency of injections or both. It must be mentioned, however, that up to the present time, such general use of the protamine insulin in diabetes, is by no means a definitely established or

unanimously agreed upon procedure. As Dr. Mosenthal has pointed out there are certain cases of diabetes whose hyperglycemia level is more or less persistent regardless of the food intake and in others where this occurs only after the ingestion of food. To combat the former a prolonged constant action of insulin would seem to be logical. To combat the latter however, the quick action of regular insulin appears more consistent. To establish any hard and fast general method of procedure covering all cases of diabetes would seem unwise and premature at this stage of our observations.

The very fact that protamine insulin has a delayed reaction time, and that this action, when once initiated in reducing the blood sugar, continues to do so over a much longer period than the regular insulin, excludes its use as an emergency measure in cases of acidosis and impending coma, where quick action is demanded. Likewise, it is preferable though not absolutely necessary that new diabetic patients, about whom no observations are obtainable with regular insulin, should not receive the protamine insulin as an initial method of treatment.

In calculating our diets for these diabetic patients receiving the protamine insulin we have followed the simple procedure of allowing one gram of protein and two and a half grams of carbohydrates per kilo of body weight. Enough fat is then added to bring the caloric intake to the required amount. The carbohydrates are so distributed during the day that one-fifth is received for breakfast, and two-fifths each for lunch and dinner. In this connection, it is of interest to point out that, the diet used in Hagedorn's original cases, averaged only about 100 grams of carbohydrates, divided into two-fifths each for breakfast and lunch and one-fifth for dinner.

Methods Advocated for Administration

Regarding the actual calculation of the amount of protamine insulin necessary in a given case, one must always remember that when this preparation is used, the

the protamine insulin itself that may possibly have an effect upon the course of treatment. *First* comes the question of the cumulative action of protamine insulin. Whether such is the case can only be conjectured and has not as yet received substantiation to make it a definite fact. It remains as a theoretical possibility and should be followed up. There is some evidence thus far which seems to indicate that such cumulative action may occur after the protamine insulin has been in use over a period of time. *Second*, whether the rate of absorption of the injected protamine insulin is the same in all persons is very questionable. *Third*, there is a possibility that the rate of liberation of the insulin, from the protamine compound, proceeds, at varying rates in the same person.

All these factors may have an appreciable effect upon the ordinary case of diabetes treated with protamine insulin but it may have quite a marked and ofttimes a very confusing effect in the case associated with marked fluctuations in the blood sugar, that has not been kept under careful observation.

Symptoms and Treatment of Overdosage

A very brief description of symptoms following an overdose should be mentioned at this point and the means employed to combat the condition. The reactions encountered with the protamine preparation are much less severe than those encountered with the regular insulin. The duration however is much longer because of the more gradual action of the protamine preparation.

Usually the first noticeable signs of intolerance or overdose is the complaint by the patient of an indefinite feeling of unrest and nervousness. They complain of feeling unusually tired as if they had engaged in some strenuous muscular exercise. Various sensory disturbances may then begin to manifest themselves in the forms of paresthesia and anesthesia, particularly a feeling of numbness about the mouth and a tingling sensation in the fingers. Visual disturbances may also occur as part of the reaction in the form of amblyopia or diplopia. There is less tendency to perspire than during the usual insulin reaction. When the

attack has been brought under control, a dull headache may persist for some time after the complete disappearance of the other symptoms and if the particular hypoglycemic reaction happens to be a severe one there is usually complete amnesia for the duration of the attack.

The management of these hypoglycemic reactions is no different from those produced by ordinary insulin except that one must remember that the reaction with the protamine is more prolonged and therefore requires more prolonged treatment. If sugar is given by mouth, small doses repeated at frequent intervals is beneficial or the administration of some food like milk and crackers which requires a longer period for absorption and hence insures a more prolonged supply, should be used to replenish the lowered blood sugar. If the reaction is very severe, the intravenous administration of glucose must, of course, be resorted to. It is quite significant to mention here that during our period of observation with protamine insulin we have encountered surprisingly few of these so-called reactions and their accompanying symptoms. None at least that have been severe enough to warrant the intravenous administration of glucose.

The whole question of insulin reaction or shock is an extremely interesting one. There are some observations that we have made both with the regular insulin and the protamine insulin which leads us to believe that the production of these so-called insulin shock symptoms is not solely dependent upon the presence of a marked hypoglycemic level. On several occasions, with the use of regular insulin, we have observed patients showing many of these clinical symptoms of insulin reaction and were very much surprised to find blood sugar values within the normal range. At the same time these symptoms completely disappeared with the ingestion of carbohydrates.

Reactions with the protamine insulin have been far less frequent and less severe than those formerly encountered with the regular insulin. We have on several occasions been surprised to note blood sugar values as low as forty-five mg without any complaints from the patient. At times only a sensation of confusion or of being dazed, would be com-

ably to regular insulin therapy, a thorough search must be made to attempt to determine whether any additional factors are responsible for the difficulty. I am stressing this point particularly for these same factors may act in exactly the same way with protamine insulin, perhaps in an even more exaggerated form and eventually lead to confusion and unwarranted discrediting of this preparation.

First An accurate consideration of the amount of physical and nervous energy expended by the patient is of utmost importance. It is not an uncommon experience to the careful observer to meet a case of diabetes which shows glycosuria when completely at rest and hypoglycemia on another day when the patient is especially active physically. Likewise the effect of nervous strain may produce similar results. In other words in the diabetic patient, proper allowance should be made for additional physical or nervous expenditures of energy, either by increasing the caloric intake for that period of additional activity or by reducing the amount of insulin allowed. This fundamental fact is very often lost sight of and may cause a great deal of confusion in an attempt to control these diabetic individuals. If this is the cause for marked fluctuations in the blood sugar, it stands to reason that very little can be expected from protamine insulin in such a case, except that it may exaggerate some of the associated symptoms, and make the problem of sugar control a more difficult one.

Second Other glandular abnormalities very often interfere materially with the proper response of an individual to the administration of insulin. Thus in a certain type of enlargement of the liver due to fatty deposition, a markedly disturbed sugar tolerance and insulin reaction is encountered. Attention to this factor was called by Hanssen⁶ recently. A common feature in this type of case is a severe form of diabetes which is difficult to control. The liver is enlarged as a result of fat infiltration, induced directly by the abnormal diabetic metabolism. This enlargement occurs only in young patients. They can be brought very well under control with protamine insulin and the condition becomes considerably improved after a certain period of treatment, as evidenced by the disappearance

of the marked blood sugar fluctuation and a decrease in the size of the liver.

Thyroid, adrenal, and pituitary abnormalities each in turn must receive proper evaluation as a possible cause for failure to control a case of diabetes with ordinary insulin. Some of the glandular disturbances, especially hyperthyroidism, make the control of the diabetes very difficult. The marked increase in the metabolic requirements are difficult to meet, and even extremely large doses of insulin prove entirely ineffectual. Surgical interference is absolutely necessary and becomes a life-saving measure. A detailed account of a typical case under this group will be given later. Under this heading may also be included certain abnormalities or peculiarities of the pancreas itself, which make the time of administration of insulin and the distribution of the dose, with respect to the daily food allowance, of considerable importance. In this connection, it has been observed that the amount of insulin generated by the pancreas itself during the twenty-four hour period has a certain diurnal variation. The least amount of activity is noted in the morning, and the greatest amount as the day progresses. For that reason the early blood sugars are quite high while the evening blood sugars are low. It has therefore been recommended by some that, one hour before breakfast, immediately after lunch, and two hours after supper is the ideal timing for the administration of regular insulin. Also in dividing the dosage of the insulin on this assumption the largest amount should be given in the morning and the rest evenly divided between lunch and supper. Practical experience with cases of diabetes confirms these experimental observations. Such variations in the function of the pancreas can very often be misinterpreted as abnormal responses and if not properly understood may lead to endless confusion. One must also mention at this point the stimulating effect upon the pancreas of small carbohydrate meals when given about an hour to an hour and a half before the regular meals. The utilization of this practical point helps considerably sometimes in the regulation of a diabetic.

There are other factors pertaining to

Case Reports

We have decided to report in detail seven of our cases because each one shows some different phase of the problem presented by the use of protamine insulin. When considered collectively, they offer a means of really evaluating the effectiveness of this preparation clinically.

CASE 1 (Chart I) This patient was a thirty-five year old German merchant, with a history of diabetes for a period of five years, who was admitted to the hospital with signs and symptoms of diabetic acidosis. His chemical blood examination on admission was 266 mg of sugar per 100 c.c. of blood, CO₂ combining power of the blood plasma was 32.8 per cent and 4.8 per cent sugar in the urine with large amounts of acetone and diacetic acid. He received intensive treatment of saline and fluids intravenously and by hypodermoclysis and adequate insulin dosage. After a period of six days he was placed on a diet of P 90 F 100 C 250 with regular insulin 30-30-30. His fasting blood sugar at this time was 250 mg per 100 c.c. of blood.

On this regime he showed marked fluctuations in his blood sugar ranging from 250 mg in the morning to fifty mg at night and excreted about twenty-two and a half gm of sugar in the twenty-four hour urine. A change in the administration of the regular insulin was then tried to 40-30-20. The marked fluctuations in the blood sugar continued ranging from 320 mg in the morning to 100 mg at night with an excretion of about eighteen and a half gm of sugar in the twenty-four hour urine specimen. The carbohydrate intake was then reduced from 250 to 200 gm with the same amount of insulin, without any evidence of checking the marked fluctuations in the blood sugar. It was then decided to use protamine insulin. His diet remained unchanged of P 90 F 100 C 200 and he received protamine insulin sixty units at 8 A.M. and twenty units at 8 P.M. After four days of this regime, the blood sugar determinations before each meal had decreased to fifty-two, one hundred twenty-five, and forty-three mg and the urine negative. The following day the patient showed signs of insulin shock with a blood sugar of thirty-four mg. This was controlled without any difficulty.

CHART III

Effectiveness of protamine insulin administered at twelve hour intervals in a case of diabetes with persistent hyperglycemia and reduction in total units of insulin made possible by use of protamine insulin therapy (Case 3)

CHART I

Method of using protamine insulin at twelve hour intervals in moderately severe diabetic who manifested marked fluctuations in daily blood sugar levels while on regular insulin, and disappearance of fluctuations with protamine insulin therapy (Case 1)

CHART II

Effect in an elderly diabetic of protamine insulin administered in morning with supplementary dose of regular insulin given with evening meal, and eventual elimination of regular insulin. (Case 2)

plained of Most of these symptoms would be controlled by the intake of food scheduled for the next meal without resorting to any additional carbohydrate intake

Our observations on this point lead us to believe that the production of insulin reaction symptoms is dependent to a

great extent upon the rate of change in the blood sugar values rather than solely upon a definite blood sugar level The sudden reduction in the blood sugar values, which are more frequent with the regular insulin than with the protamine insulin seems to confirm and explain the above mentioned contention

of protamine insulin one hour before breakfast and ten units of regular insulin at 6 P.M. It is very interesting to note the gradual lowering of the sugar curves done at several day intervals, while on this regime. The last one performed was after the patient had been taking only the prota-

a check revealed a fasting sugar of 234 mg per 100 cc of blood with five gm of sugar in the urine. It was then decided to change the regular insulin administration to 40-20-20. After an additional seven days on this treatment the fasting blood sugar was still 222 mg. Another increase in the

CHART V

mine insulin as one dose in the morning. Comparison of these different sugar curves shows the striking changes and resultant establishment of the blood sugar on a much lower level and without wide fluctuations during the twenty-four hour period.

CASE 3 (Chart III). Patient was a fifty-eight year old German sailor who developed a bronchopneumonia, and in addition had a blood sugar of 235 mg per 100 cc of blood and CO₂ combining power of the blood plasma of forty per cent vol with forty gm of sugar in the urine. He was placed on a diet of P 50 F 50 C 100 with regular insulin 30-10-30. After four days

regular insulin was then made, so that the patient was receiving 40-20-30 units and after a few days his urine became sugar free. It was then a question of increasing his diet and also of the convenience of this patient's receiving three injections of regular insulin a day after leaving the hospital. We felt that the use of protamine insulin might be of considerable help. The patient's diet was accordingly increased to P 90 F 60 C 175 and protamine insulin given forty units in A.M. and twenty units in P.M. After six days of this regime the patient reported he felt exceptionally well and his fasting blood sugar was 100 mg with no sugar in the urine. The protamine

Inasmuch as the patient complained of being hungry most of the time on the diet allowed, it was decided to increase the diet rather than decrease the protamine insulin. Patient received P 90 F 120 C 300 with sixty units of protamine at 8 A M and twenty units at 8 P M. There were no

of precordial pain with radiation down the left arm and weakness. The patient had not been receiving insulin prior to admission to the hospital. The blood sugar on admission was 294 mg per 100 c.c. of blood and CO₂ combining power of the blood plasma forty-nine per cent vol. Her

CHART IV

Effectiveness of protamine insulin, in moderate case of diabetes, administered together with supplementary dose of regular insulin one hour before breakfast, with eventual elimination of this supplementary regular insulin (Case 4)

marked fluctuations in the blood sugar noted any further and blood sugars before each meal showed 129, 136, and 125 mg respectively. The patient was then discharged, taking only one dose of seventy units of protamine insulin in the morning with the same food intake.

CASE 2 (Chart II) Patient was a seventy-eight year old female with a history of diabetes of long standing. At the time of admission to the hospital she was suffering from a rather marked cardiac decompensation. In addition she complained

urinary sugar was twenty-four gm during the twenty-four hours. A diet consisting of P 60 F 50 C 150 was allowed at this time with regular insulin units 25-0-15. After a period of about ten days, her blood sugar values before each meal were 271, 308, and 228 mg with sugar excretion reduced to fourteen gm for the twenty-four hour period. It was then decided to institute protamine insulin therapy rather than increase the regular insulin dosage, or decrease the carbohydrate content of the diet. Accordingly she received thirty units

tinued to have a hyperglycemia (244 mg) and glycosuria. Rather than decrease the diet or increase the dosage of regular insulin, we thought that protamine insulin should be tried. Accordingly the diet was kept the same and the morning dose of forty units regular insulin was continued, and in addition twenty units protamine insulin allowed at 6 P.M. After two days the patient had an insulin reaction at 2 A.M. and as a result the insulin dosage was further reduced to twenty units regular in A.M. and thirty units protamine at 6 P.M. The patient continued to show marked improvement with absence of hyperglycemia or glycosuria, so that after ten days the insulin was further reduced to twenty units regular in A.M. and twenty units protamine at 6 P.M. The patient's weight had increased to 114 lbs and he was sent home on the same caloric intake as above with fifteen units regular insulin in A.M. and twenty units protamine insulin at night.

CASE 6 (Chart VI) This patient was a thirty-one year old male who was admitted to the hospital October 19, 1936, complaining of polyphagia, polydipsia, and polyuria of six months duration. He had lost approximately thirty-five pounds during this period. There was nothing significant in his past history, except that eight years previously he had had a G.C. urethritis which lasted about two months. The patient was in the habit of consuming for the previous ten years, about half a pint of whiskey and about three quarts of beer daily. He was unmarried and there was no family history of diabetes obtained. Examination revealed a well-developed adult male who showed signs of considerable recent weight loss. His pupils were regular, equal, and reacted normally to light and accommodation. His teeth were in poor condition and showed marked alveolar recession. Pharynx was reddened. There was no thyroid enlargement. Lungs were negative. The heart was slightly enlarged to the left and the heart sounds were regular and of good quality. Reflexes were normal. On admission his fasting blood sugar was 188 and his urine contained 39 per cent sugar. He received a diet of P 70 F 85 C 150 and regular insulin 10-10-5. His blood sugar continued to be elevated and the glycosuria remained practically the same. On October 27, his fasting blood sugar was 238 mg and the urine showed 18 per cent. The same diet was maintained and the insulin dose was increased to 20-10-15. Following this change some improvement was noted in his

condition by a further reduction in the fasting blood sugar to 185 mg. The glycosuria remained about the same however. The regular insulin was further increased on November 2 to 25-15-20. The hyperglycemia and glycosuria, however, was not greatly improved by this regime, so that it was decided to start the use of protamine insulin in this case. Accordingly forty units of the protamine and twenty units of the regular insulin were given one hour before breakfast. The same diet was maintained. After a period of five days blood sugar determinations before each meal showed 133, 82, and 80 mg with 0.4, 0.6, and 0.4 per cent sugar in the urine specimens from supper to breakfast, breakfast to lunch, and lunch to supper. After an additional eight day period on the above regime it was noted (November 17) that the blood sugar values before each meal had increased to 137, 140, and 124 mg and that the urine from supper to breakfast contained 28 per cent sugar. It was therefore felt that this patient could tolerate an increase in the insulin dosage. Accordingly he was given forty-five units of protamine and twenty units of regular insulin one hour before breakfast. After a six day period, his blood sugar values before each meal were seventy-six, forty-four, and sixty-seven mg. The patient experienced a mild insulin reaction which coincided with the low blood sugar value. This was very easily controlled. It was therefore decided to allow only the forty-five units of the protamine in the morning dose and discontinue the use of the regular insulin entirely. Four days later the blood sugar determinations before each meal showed an increase to 119, 185, and 125 mg with some glycosuria in the afternoon and evening specimens of urine. It was felt that the dose of regular insulin had been discontinued too abruptly for this particular case, and so the patient was given fifty units of protamine and ten units of regular insulin in the morning and on this regime and with the same food intake blood sugar determinations on December 2, 1936 showed 133, 53, and 56 mg with complete disappearance of the glycosuria. The patient was finally discharged in about three days, taking only fifty units of protamine insulin one hour before breakfast.

CASE 7 (Chart VII) This case was one of juvenile diabetes in a boy sixteen years of age who was readmitted to the hospital because of difficulty in regulating his diabetes at home. He had been in the hospital one year previously for treatment. Since his discharge he had been followed

insulin was accordingly reduced to twenty units in A M and twenty units in P M. Thus this patient who on a diet of P 75 F 60 C 120 and ninety units of regular insulin a day, still persisted in showing a considerable hyperglycemia, became normal with the use of only forty units of protamine insulin a day, in spite of the fact that his diet was increased to P 90 F 60 C 175.

CASE 4 (Chart IV) This patient was a fifty-two year old female who was admitted to our Gynecological Service, complaining of a sensation of some protruding mass in the vagina. This condition had been getting progressively worse for the past ten years and the patient had decided to enter the hospital for surgical relief. Her last menstrual period occurred seven months previously. The patient's diabetic condition was discovered three years previously and since that time she has been on a restricted diet with the use of fourteen units of regular insulin at night. The patient states however that she has not been checked from time to time regarding her blood sugar values and that glycosuria was present under the above regime. There was nothing significant in her past or personal histories. Her family history revealed that her mother had been a diabetic.

On examination, she revealed a third degree prolapse of the cervix and uterus through the vagina and operation was advised as soon as the patient could be properly prepared for it. At the time of admission November 5, 1936, her fasting blood sugar was 286 mg per 100 c.c. of blood and CO₂ combining power of the blood plasma 46.2. Her urine showed a large amount of sugar (25%) but no acetone or diacetic acid. She was given intensive therapy with regular insulin and five days later her blood sugar was reduced to 200 mg and her urine sugar free. She was operated upon November 10 and a vaginal hysterectomy performed. She made an uneventful recovery and it was thought that protamine insulin should be tried in this case. She had been placed on a diet of P 60 F 60 C 120 with insulin 20-0-20 (November 13). At this time her blood sugar was 215 mg and she excreted nine gm of sugar in the twenty-four hour urine specimen. On November 17 her fasting blood sugar was 196 mg. The diet of P 60 F 60 C 120 was continued with regular insulin 20-0-20. On November 25 blood sugar determinations before each meal showed 169, 163, 180 with the urine negative. Because the patient did so well on the regular insulin it was decided to allow

only twenty units of the protamine and ten units of the regular insulin in the morning before breakfast. This approximation however was not justified for on November 30 blood sugar determinations before each meal showed 177, 194, and 192 mg with considerable glycosuria in all three urine specimens. The insulin dosage was then changed to twenty-five units of protamine alone and after an additional four day period, her blood sugar values before each meal were 127, 154, and 154 mg. The patient has been getting along very nicely ever since with the use of twenty-five units of protamine insulin and approximately the same diet.

CASE 5 (Chart V) This case is of particular interest as demonstrating the marked disturbance that can take place in the carbohydrate metabolism of a diabetic patient with the onset of hyperthyroidism. The patient was a thirty-one year old male with a diabetic history dating back twelve years. It is of interest to note that at that time I did a basal metabolism test and found it to be +5%. Since that time the patient had been getting along on a fairly liberal diet with twenty units of regular insulin twice a day. Five months prior to the present admission to the hospital, the patient began to complain of nervousness, palpitation, loss of weight, and fatigue. His weight loss during the five months period was thirty-five pounds. On admission to the hospital his weight was 118 lbs. Fasting blood sugar 263 mg per 100 c.c. of blood and B M R +77%. He was given five minims of Lugol's solution three times a day and a diet of P 90 F 150 C 250 with insulin 30-15-30. After ten days the B M R dropped to +30% but his weight had decreased further to 107 lbs. It was therefore decided to increase the caloric intake and also the amount of regular insulin, in order to stop the marked weight loss. Accordingly his diet was increased to P 60 F 180 C 350 with regular insulin 40-20-20. In spite of this therapy the fasting blood sugar (June 3, 1936) remained elevated at 312 mg and the weight showed a further decrease to 103½ lbs. His B M R. had risen to +60% and his condition was considered very unfavorable. It was decided after considerable consultation, to attempt a subtotal thyroidectomy on the patient. This was performed on June 25 and was effective in lowering the B M R. and eliminating most of the hyperthyroid symptoms. After a stormy convalescence the control of the diabetes was again attempted. Accordingly, the patient was given a diet of P 70 F 120 C 250 with regular insulin 40-10-20 units. The patient however con-

provement however was observed in this respect, so that the blood sugar which had fluctuated from 250 mg in the morning, to fifty mg per 100 cc of blood at night was changed to a fluctuation from 320 mg in the morning to 100 mg at night. The glycosuria however was still present. The next step that was tried was reducing the carbohydrate intake from 250 to 200 gm and keeping the insulin administration the same. This likewise had no beneficial effect on the control of the diabetes.

Maintaining the same dietary factor, we then switched this patient to protamine insulin exclusively. He received sixty units of the protamine insulin at 8 A.M. and twenty units at 8 P.M. Two definite and striking effects were noted as a result of this change: a marked lowering and flattening out of the daily

blood sugar curve, and a complete disappearance of the glycosuria. Thus we were able to accomplish with eighty units of the protamine, that which was practically impossible with ninety units of the regular insulin. Incidentally the number of injections were also reduced from three to two per day. With further treatment and without any increase in the dose of the protamine insulin the dietary factor could finally be increased to P 90 F 120 C 300, without precipitating either hyperglycemia or glycosuria. This case shows the method which we have described (No 4) wherein the protamine insulin is administered at twelve-hour intervals.

In Case 2 (Chart II), the patient at the beginning of our period of observation was receiving a diet of P 60 F 50 C 150 and insulin units 25-0-15. Her

CHART VII

Protamine insulin in severe form of juvenile diabetes, with resultant effectiveness of single dose of protamine insulin administered once a day before breakfast with consequent reduction in total daily insulin requirement. (Case 7)

CHART VI

Effect of protamine insulin therapy in case of moderately severe diabetes with administration of seventy per cent of total daily units as protamine insulin and thirty per cent as regular insulin given as separate injections, one hour before breakfast and the gradual elimination of regular insulin (Case 6)

by our outpatient department. Recently he began to show considerable glycosuria and admission to the hospital was advised.

On admission November 19, 1936, his fasting blood sugar was 290 mg and his urine showed three per cent sugar. He was placed on a diet of P 70 F 70 C 200 and given regular insulin 35-20-25. After a six day period, the blood sugar values before each meal were 204, 165, and 85 mg with considerable sugar present in the corresponding two urine specimens. It was decided to see how this patient would respond to protamine insulin. He was accordingly given sixty units of the protamine and twenty units of the regular insulin as separate injections one hour before breakfast. Seven days later, blood sugar determinations showed a marked improvement and were found to be 152, 137, and 41 mg. The glycosuria was greatly reduced. The patient experienced slight insulin reaction coinciding with the blood sugar of forty-one mg but the intake of the evening meal gave adequate relief without the need of any additional carbohydrate intake. It was therefore decided to reduce the regular insulin to only ten units and maintain the

protamine insulin at sixty units. After a four day period (December 5) the blood sugar values taken before each meal were 133, 53, and 56 mg and no sugar in the urine. The patient was then given sixty-five units of the protamine as one dose, one hour before breakfast. There was complete control of the glycosuria and very little change in the blood sugar from the previous determinations.

Discussion

By examining carefully the observations noted in our selected group of case reports, the effect of protamine insulin under a variety of conditions may be appreciated. Thus, Case I shows the course of a moderately severe diabetic who with an intake of P 90 F 100 C 250 and insulin 30-30-30 showed marked fluctuations in the blood sugar during the day with considerable glycosuria. It was thought that perhaps by changing the insulin to 40-30-20 these fluctuations might be eliminated. Only a slight im-

his glycosuria completely cleared and the patient showed signs of a hypoglycemic reaction. The dosage was further changed to twenty units of regular insulin in the morning and thirty units of protamine with his supper. After another ten-day period this was further reduced to twenty units regular in A.M. and twenty units protamine in P.M. and finally to fifteen units regular and twenty of the protamine. The method employed in this case is that which we have described under procedure No. 1 and is similar to the one used by the original investigators.

In Case 6 (Chart VI), the effect of the protamine insulin is very well demonstrated. There are two points that we wish to particularly stress and which are very well illustrated by this case. The first is the marked sensitiveness that is noted in the blood sugar equilibrium as one nears the level of the required amount of protamine insulin. Thus it may be noted that increasing the protamine insulin five units precipitated hypoglycemic reactions as noted in Chart VI on November 23, 1936. We have found thus far that this sensitive upper limit, when once disturbed, causes a considerable degree of vasculature in the blood sugar levels which sometimes causes difficulty in restoring an equilibrium. It is for that reason that we prefer to begin with too small a dose of the protamine rather than a too large one. This case also demonstrates the fact that when the supplemental dose of regular insulin is twenty units it is far better to effect the reduction and omission of this dose gradually rather than at one time. Thus it was necessary to resume the use of ten units of the regular insulin for a period of time before finally replacing it by an additional five units of the protamine insulin.

Another point which we would like to discuss is the question of low blood sugar values and their accompanying symptoms. It has been our experience to encounter rather low blood sugar values, such as the 44 mg. reading in this particular case on December 2, 1936 without very marked subjective symptoms. This observation we have noted on several occasions, since beginning the use of the protamine insulin. This phenomenon may be explained on the basis of the rate of change of the blood sugar concentration

rather than on the actual blood sugar level. We wonder whether the symptoms of insulin reaction which we have observed with the regular insulin may not be due to the rapid drop in the blood sugar level. This phenomenon is certainly extremely interesting and requires a good deal of further study.

In Case 7 (Chart VII), the response and control of a case of juvenile diabetes with protamine insulin alone is very clearly demonstrated. There are two striking advantages of this procedure that can be noted in the study of this case. The reduction of the number of injections from three to one a day and also a reduction in the total amount of the protamine insulin as compared to that of the regular insulin. Here again, we have an opportunity to see that it is far better to gradually reduce the dose of the regular insulin, when large, than to stop its use suddenly. It results in a more even course and offers less possibility of upsetting the carbohydrate equilibrium.

This particular patient had found the administration of three doses of regular insulin a great hardship because of his school work. He was indeed very grateful for the opportunity afforded by the protamine insulin to diminish this to one injection administered in the morning.

It can therefore be stated that great possibilities have presented themselves to the medical profession with the perfection of this new form of insulin. Of course the use of the regular insulin in the moderate case, has offered very little difficulty but even here, if one can obtain a decrease in the number of injections necessary during the twenty-four-hour period, then something very practical and helpful to the diabetic patient has been accomplished. Our experience leads us to feel that all these cases of so-called moderate diabetes can be benefited in this way by the use of this preparation.

The protamine insulin, however shows the most striking effect in the more severe forms of this disease, particularly in those cases which show marked fluctuations in the blood sugar that cannot be effectively controlled without either reducing the carbohydrate intake materially or by administering large and frequent doses of insulin. This is especially true in those cases often referred to as "Insulin wasters."

fasting blood sugar at this time was 294 mg per 100 c c of blood, and she continued to show considerable glycosuria. At the end of ten days of the above treatment we found her fasting blood sugar still elevated at 271 mg and she still had considerable glycosuria. Instead of increasing the dose of regular insulin or decreasing the diet we felt that the change to protamine should be effected without any further delay. Accordingly she was given the same diet and thirty units of protamine insulin one hour before breakfast and ten units of regular insulin at supper time. Eventually this dose could be reduced to only the thirty-five units of protamine administered one hour before breakfast with the resulting disappearance of the hyperglycemia and glycosuria. The method of administration of the protamine insulin which this case illustrates is the one listed as No. 2 in our description. This method represents the reverse of that used by the original investigators. The number of injections was eventually reduced to one during the twenty-four-hour period with a resultant flattening out of the blood sugar curve throughout the day and the elimination of the glycosuria.

In Case 3 (Chart III), one may observe what can be accomplished in the less severe form of diabetes, with the use of the protamine insulin. This patient on a very low diet of P 50 F 50 C 100 and regular insulin of 30-10-30 continued to show a hyperglycemia with a slight glycosuria. The dose of the regular insulin was increased to 40-20-20 and then to 40-20-30. He became sugar free, but persisted in showing a moderate hyperglycemia. The patient complained bitterly of being hungry most of the time and really required a greater caloric intake. It was therefore decided to try the protamine insulin therapy. His diet was accordingly increased to P 90 F 60 C 175 and protamine insulin forty units at 8 A M and twenty units at 8 P M were given. The improvement with this was so excellent that after six days his hyperglycemia had cleared and we were able to further reduce the protamine intake to twenty units at 8 A M and twenty units at 8 P M. Unfortunately the patient who was a sailor insisted upon

returning to his ship, so that further observation could not be made in an attempt to further reduce the protamine insulin dosage to one injection a day which we had hoped to do.

In Case 4 (Chart IV), the patient responded well to regular insulin therapy which was used to prepare her for operation. The observations on this case are merely presented to show the advantages gained by placing this patient on protamine insulin therapy. With a diet of P 60 F 60 C 120, the administration of forty units of regular insulin given as two doses, one in the morning and one at night, was sufficient to control the patient's glycosuria. It was desired, however, to increase this patient's diet to P 60 F 100 C 150 and we then instituted the protamine insulin therapy. This case shows strikingly how nearly accurate our seventy and thirty per cent approximations of the doses of protamine and regular insulin is. This can be seen by the fact that our attempt to use only twenty units of the protamine and ten units of the regular insulin was not satisfactory. In spite of the increase in the diet, a dosage of protamine insulin, ten units less than that of the total regular insulin that had been used in this case was ample to control the diabetic condition. In addition to this a decrease in the number of daily injections from two to one per day was accomplished.

The observations in Case 5 (Chart V), are extremely interesting and illustrate the marked disturbance and difficulty that may be encountered in the control of diabetes in the presence of hyperthyroid symptoms. Following the thyroidectomy the diabetes improved, but there was then noted marked fluctuations in the blood sugar level, which were rather difficult to control with the regular insulin. After thyroidectomy, the patient was put on a diet of P 70 F 120 C 250 and regular insulin of 40-10-20 units, under which regime he still continued to show a rather marked hyperglycemia and glycosuria. A change was made using forty units of regular insulin one hour before breakfast and twenty units of protamine, with his supper. This meant a reduction from a total of seventy units to a total of sixty units. The improvement was so pronounced that within forty-eight hours

WHAT THE TREATMENT OF SYPHILIS ACCOMPLISHES

PAUL A. O'LEARY, M.D., *Rochester, Minn*
Section on Dermatology and Syphilology, The Mayo Clinic

The modern treatment of syphilis became popular approximately only twenty years ago, accordingly, efforts to evaluate adequately the results of the use of the remedies employed to date have not been feasible. In fact appraisals of the results in cases in which patients have been treated during this twenty-year period are inadequate and will continue to remain so until we have had the opportunity to observe the results of treatment for a period equivalent to the life expectancy of man rather than the average duration of syphilis in man.

There is need, however, for a study of the results of treatment up to the present time in order to permit us to adopt in practice or to amplify the therapeutic procedures which have shown the outstanding results. It was with this purpose in mind that the Coöperative Clinic Group* was organized in this country eight years ago. Case records from the syphilis clinics of five universities were pooled in Washington under the guidance of the United States Public Health Service, and the results of treatment, as applied during the past twenty years to patients with the various manifestations of syphilis, have been and are in the process of being appraised.

The Coöperative Clinic Group's material now consists of approximately 75,000 case records, and it is data from the published reports of these studies that I shall use as the basis for this discussion of what the modern treatment of syphilis actually has been accomplishing. I realize that many of you are concerned with

the social, economic, clerical, and technical phases of syphilis, whereas others of you are concerned with the public health and therapeutic aspects of the disease. Irrespective of your mission in the field of public health work, I believe you also have some interest in what the treatment of syphilis accomplishes and what may be anticipated, both good and bad, from the present day therapeutic programs.

When we may anticipate cure and when the relief of symptoms is all we may expect are questions which are of concern to us who are directly or indirectly interested in the patient with syphilis. The answers to these questions are made possible by surveys of the records of large groups of cases observed over periods of years. However, the weakness in such an undertaking lies in the fact that the average patient with syphilis is a migratory "bird," flitting from clinic to clinic, who is readily scared off by a reaction to treatment, one who usually acquires the disease at an age when there is no thought of responsibility for the future, and one who migrates in search of work or because of wanderlust, unmindful of the fact that irregularity and inadequacy in treatment result in serious sequelae. Such instability on the part of these patients demands that, in order to observe the results of treatment over a period of ten to fifteen years, a large series of cases in which the patients have been treated be used.

There were 6807 cases in which patients started treatment for acute syphilis in the coöperating clinics. By the end of the second year only 1360 of these patients remained under treatment and observation, and by the fifteenth year all but fourteen of these patients had been lost track of. The value of statistical studies under such conditions is materially minimized. Accordingly, it is obvious why enthusiastic and energetic follow-up

* This group is composed of Dr. Joseph Earle Moore, Johns Hopkins University; Dr. John H. Stokes, University of Pennsylvania; Dr. Udo J. Wile, University of Michigan; Dr. H. N. Cole, Western Reserve, and myself. The chairman is Dr. Thomas Parran, Jr., Surgeon General, U. S. Public Health Service, and the group has the cooperation of the following Assistant Surgeon Generals: Dr. John McMullen, Dr. R. A. Vonderlehr, and Dr. Taliaferro Clark. The statistical survey was made under the direction of Lida J. Usilton, M.A.

Read at the Annual Conference of Health Officers and Public Health Nurses of the State of New York, Saratoga Springs, June 22 to 25, 1936

Emphasis must again be made on the fact that in using the protamine insulin, one must avoid the error of changing too many factors at any one time or of making too frequent changes in any given case. This point cannot be stressed too much. Thus when the change is made from the regular to the protamine insulin, the dietary factory should not be changed at the same time. Likewise a sufficient period must be allowed for observing the effects of this change, before attempting additional ones. If these fundamental principles are overlooked, wide fluctuations in the blood sugar values will result with endless confusion and disappointment. From a practical point of view, it is much better to begin with too small a dose of the protamine insulin rather than a too large one. A fairly good and practical method of determining a patient's response to this treatment is observed when blood sugar determinations before each meal are made, about every fourth or fifth day of the observation period and the quantitative sugar is determined in the urine specimens collected for the periods between these meals, i.e., from supper to breakfast, breakfast to lunch, and lunch to supper.

To formulate a general hard and fast rule or method of procedure which will fit every case of diabetes, is just as foolhardy as attempting to set up a standard, stereotyped method of treating pneumonia. It just cannot be done. Only the general principles of the procedure can be formulated which must depend upon the general knowledge of the subject and the clinical acumen of the physician in charge, for its modifications and application in the individual case.

Summary and Conclusions

1 Diabetics showing marked fluctuations in the blood sugar, or those associated with certain complicating factors, as hepatic enlargement, hyperthyroidism,

etc., can be controlled better by protamine insulin than by regular insulin.

2 Cases of diabetes, showing persistent hyperglycemia or where it is desired to diminish the frequency of injections, should receive protamine insulin, in an attempt to accomplish this result.

3 Protamine insulin should not be used in cases of acidosis or impending coma or those complicated by surgical conditions.

4 We have not as yet used protamine insulin as an initial form of treatment in previously unobserved cases of diabetes.

5 When changing from the regular to protamine insulin, we have found that good results may be obtained by giving seventy per cent of this amount as protamine insulin and the balance as regular insulin, both administered about one hour before breakfast, as separate injections.

6 After a period of four to seven days, if the morning urine is sugar-free, we discontinue the dose of regular insulin. If the morning glycosuria persists, we increase the protamine insulin or continue the dose of regular insulin and then attempt to gradually reduce this dose.

7 It has been our experience that if the dose of regular insulin used with the protamine is more than ten units, gradual reduction of this dose gives better results than discontinuing its use all at once.

8 Increases or decreases in protamine insulin should consist of only five units at a time.

9 Too many factors should not be changed at one time, nor should the effected changes be made at too frequent intervals.

10 It seems possible that the more gradual reduction of the blood sugar to low levels may explain the mild symptoms of insulin reaction that we have obtained with comparatively low blood sugar values, in cases treated with the protamine insulin.

more injections of arsphenamine and twenty or more injections of bismuth or mercury, the incidence of satisfactory results varied from sixty-four to eighty-six per cent, depending on the duration of the disease when the treatment was started. The system by which these remedies were given was also shown to be a vital factor in the outcome of treatment. The patients who were treated by the continuous* system for a year or more obtained cures in eighty-four per cent of cases, those treated intermittently were less successful, while those treated by an irregular system were rewarded by cure in only fifty-five per cent of cases. Patients whose treatment was begun during the first week of the disease, when the chancre was present but the blood test had not as yet become positive, showed the highest incidence of cure (86 per cent), the next most successful results were noted among those who had a full crop of secondary skin lesions, whereas for those who had a chancre and a positive blood Wassermann but in whose cases the secondary rash had not developed, the incidence of cure dropped to sixty-four per cent.

The recent report of the survey of the health organization of the League of Nations indicated that the intermittent system of treatment as carried out in Denmark resulted in a slightly higher incidence of cure than the continuous system of treatment had produced in this country. This is in a measure due to the fact that forty injections of arsphenamine, with a heavy metal, comprised a minimal cure, and that the health laws in Denmark require and enforce the treatment of all patients with early syphilis until they are cured. A comparison of the results of the continuous versus the intermittent

system of treatment in the League report was not conclusive because the continuous method of treatment is essentially an American development and has had comparatively little application in European clinics. Our recent experience with the continuous system, using a minimum of forty injections of arsphenamine and a heavy metal, indicates that the incidence of cure will be well over ninety per cent for patients with acute syphilis.

Although the system of treatment used is an important factor, the type of arsphenamine given and the dosage employed are likewise potent influences in the outcome of treatment. The old arsphenamine (606) was shown to be a more valuable agent than neoarsphenamine. Arsphenamine has a higher therapeutic index and a lower complication rate than neoarsphenamine. This does not mean that neoarsphenamine is an inefficient drug but merely that its present day popularity is the result of its comparatively simpler technical advantages and not of any superior therapeutic effects. The use of eight injections of neoarsphenamine as compared with six injections of arsphenamine tends to equalize the value of these drugs. For several years it has been the practice in some clinics to give small doses of the arsenicals in an effort to minimize the complications of treatment. This practice has resulted in a lowering of the therapeutic results in these institutions, as shown by a higher percentage of Wassermann-fast cases and a greater incidence of recurrent lesions in the skin and mucous membranes.

A comparison of the value of bismuth and mercury shows that bismuth is the superior of the two agents. The combination of arsphenamine and bismuth given by the continuous system resulted in the highest incidence of cure in cases of acute

Continuous treatment is defined as uninterrupted treatment with an arsphenamine and a heavy metal, whether administered in alternation or simultaneously. The distinctive feature of this scheme is its uninterrupted character, without purposeful rest periods. In this group were included patients receiving prolonged treatment, even though the continuity was broken toward the last by a lapse in treatment.

Intermittent treatment is that given with arsphenamine and a heavy metal, the continuity of which is interrupted by short intervals of rest throughout treatment, whether purposeful or not. The distinctive feature is the rest interval of four to six weeks after each course of treatment.

Irregular treatment is defined as treatment with an arsphenamine and a heavy metal which follows neither of the systems heretofore described, either consistently or approximately.

workers, fired with the facts that show why intensive treatment of early syphilis is essential, are potent cogs in the machinery of every therapeutic organization

The five clinics which comprise the cooperative group were selected because their case records were complete, in that they had recorded not only the kind and amount of treatment administered, but had also included serologic data on the blood and spinal fluid. There are many clinics in this country in which numerous patients are treated each year but their records are not complete and do not permit a statistical study of the results of treatment. The need for accurately recording the treatment and serologic data in a manner which will be legible and understandable a decade or two hence is therefore obvious. Not only interested but efficient and earnest clerical assistants are of paramount importance for such a successful record system.

I also believe that the creating of technical assistants is essential to the modern syphilologic clinic. These technicians should be taught not only the art of intramuscular and intravenous injection, but also the preparation of the materials for administration, the reactions which may follow, and the measures which counteract such manifestations, in addition they should be familiar with the contraindications for the use of the remedies employed. Such technicians, usually graduate nurses, have a status similar to that of the nurse-anesthetist. Many patients discontinue treatment for syphilis because of reactions to treatment resulting from a poor intravenous or an indifferent intramuscular technic of administration. Such difficulty may readily be overcome by the development of a dexterous technician who takes pride in her ability to get the needle into the vein at the first attempt and is chagrined when she produces infiltration of tissues at the site of injection. A knowledge of the impending signs of intoxication from the heavy metals may readily be taught such assistants. The supervision of dosage by physicians, the intervals between treatments, and the type of the remedy used is, of course, necessary.

The aim of treatment for syphilis may be said to be six-fold

- 1 Protect the members of the community from patients who are in the infectious phase of the disease
- 2 Cure when possible.
- 3 Increase the patients' life expectancy
- 4 Hold the disease in abeyance.
- 5 Relieve symptoms and discomfort if the other aims are not possible to achieve.
- 6 Prevent transmission of the disease to the patients' progeny

Although the patient with acute syphilis is highly infectious, the patient with latent or quiescent syphilis is but rarely so, and the patient with late syphilis is to all practical purposes incapable of transmitting the disease.

It is common knowledge that arsphenamine renders a patient with acute syphilis noninfectious, and the health laws of most of the states recognize this fact. However, in these same states legal codes are often inadequate because they fail to make provision for the few patients who do not permanently retain this noninfectious state. The term "chronic relapser" has been applied to these patients, and they are of great concern to you and me who are interested in public welfare because they are an unwitting source of many new cases of syphilis. Stokes,^{1,2} in reporting the cooperative clinics' survey, showed that in twelve per cent of the patients with early syphilis, infectious relapses on the skin and mucous membranes developed after treatment. However, eighty-seven per cent of these patients had received an inadequate amount of treatment, or less than twenty injections of arsphenamine. Of those patients who were adequately and intensively treated, the infectious lesions recurred in only six per cent of cases. It is to be emphasized that irregular, inadequate, and desultory treatment accounted for most of the relapses, and practically all of the infectious lesions reappeared during the first two years of the disease.

I believe it is universally agreed by syphilologists that acute syphilis is curable. It is unfortunate that our present-day knowledge limits such a statement only to the acute phases of the disease. The number of injections of arsphenamine and bismuth or mercury and the system by which the treatment is given are the potent factors in the production of cure. Among patients who received twenty or

a diagnosis. In other words the blood tests may be negative or positive in cases of latent syphilis.

The early phase of latency is especially significant, as it has been shown that the first four years of the disease is the period when the patient gives evidence of attempting to control the disease, or else that he is totally lacking in any such defensive mechanism. It might well be said that the importance of latency does not lie so much in the recognition of the latent state as in the fact that in the process of making such a diagnosis the status of the patient has been completely surveyed and that he has been found to be free of the manifestations of syphilis, because if presumptive clinical signs or symptoms of syphilis are demonstrated, the diagnosis of latent syphilis is immediately discarded.

Moore¹ reported the Cooperative Clinic Group's study of latent syphilis. He noted the probable outcome in cases of latent syphilis in which patients were not treated and found that about a third of the patients who were not treated during latency were cured, another third retained a positive blood test but remained free of symptoms for the rest of their lives and the remaining third manifested either benign or severe manifestations of the disease. When a study was made of the results of treatment in a group of patients with latent syphilis it was found that in eighty-five per cent of the cases in which patients were treated with bismuth alone, receiving forty injections or more, the serologic and clinical findings were negative. The results of bismuth therapy alone were about twice as good as from any combination of arsphenamine and bismuth or mercury. However, it is recommended that arsphenamine be given in conjunction with bismuth to those patients the latency of whose condition is of four years' or less duration, because of the more satisfactory control of the infectiousness.

A matter worthy of special comment is that of pregnancy in cases of latent syphilis. In seventeen per cent of women with latent syphilis the disease interrupted pregnancy or resulted in a syphilitic child. Hence, for women with this type of syphilis, irrespective of the Wassermann test or irrespective of the amount of treatment received prior to their hav-

ing become pregnant, adequate treatment should be given throughout pregnancy.

Cole⁵ has interpreted the Cooperative Clinic Group's study on the influence of syphilis in pregnancy. He has shown that a negative Wassermann in the case of a syphilitic woman does not assure her of a nonsyphilitic child, although the percentage of normal children born to these women is greater than to those who have a positive Wassermann.

When treatment for syphilis is started before the fifth month of pregnancy, ninety-one per cent of the children born are nonsyphilitic, whereas if treatment is begun after the fifth month of the pregnancy, thirty-eight per cent of the children born will have the disease. It is accordingly essential that treatment be given early and adequately during pregnancy—the earlier the better and the more adequate the better for the child's welfare since these women tolerate both the arsenicals and metals very well and there are but few instances of toxic reactions. It is especially urgent that intensive treatment be given the syphilitic woman throughout each pregnancy whether the Wassermann is positive or negative. Contrary to former impressions, pregnancy does not protect a syphilitic woman from clinical progression or relapse of the disease. In fact, it does the reverse and tends to predispose to an undermining of her resistance to the disease in the late stages.

The study of the two most common serious sequelae of the disease, namely, cardiovascular syphilis and neurosyphilis, has shown that our present methods of treatment are unable to cope adequately with these complications once they have become manifest. However, Cole,⁶ speaking for the Cooperative Clinic Group, showed that the modern treatment during the early phase of syphilis is highly efficient in preventing the development of cardiovascular disease. In 3,641 cases in which patients were adequately treated early in the course of the infection, syphilis of the aorta and heart valves developed in less than one per cent of the cases. On the other hand of the group who came to the clinics with definite signs of cardiovascular syphilis, sixty-two to eighty-four per cent, depending on the type of heart disease present, had never

syphilis of any of the therapeutic combinations

Why do certain patients with acute syphilis who adhere to the therapeutic program in all details fail to obtain a cure? Why do some patients with acute syphilis manifest signs of general paralysis of the insane or syphilitic heart disease several years after acquiring the disease in spite of strenuous and arduous therapeutic measures? I might also ask, why do certain patients who receive little treatment and some who receive no treatment at all obtain serologic and clinical "cures"? In short, why does treatment sometimes fail to produce "cures"? In answering these questions there are three factors, common to all infectious disease, which must be discussed, namely, (1) the causative organism, (2) the treatment, and (3) the patient

The organism which produces syphilis is known as "*Spirochaeta pallida*." There has been considerable discussion in the past apropos the existence of various strains of the *Spirochaeta pallida*. For example, it has been shown in the laboratory animal that a certain strain of the organism has a special affinity for the central nervous system, while other strains may predispose to the development of lesions of syphilis in the heart, skin, or liver. The hypothesis drawn from this concept infers that if a group of men are infected by one prostitute, they all should eventually manifest the same complications of syphilis. In clinical practice, however, this does not happen and proof is still lacking that there are specific strains of *Spirochaeta pallida*.

The second factor in the discussion as to why all patients treated for early syphilis are not cured is that of treatment. There is ample evidence available that the arsphenamines, in combination with a bismuth or mercurial preparation, not only prevent patients with acute syphilis from disseminating the disease in their communities, but also that such treatment actually cures a high percentage of the patients who are adequately treated. The evidence is incontrovertible that cures occur following the use of these remedies in a much higher proportion of cases than from any other scheme of treatment or from any other therapeutic agent thus far described. The arsphenamines and heavy metals fail to produce cures in all cases, probably because in those patients for whom treatment fails there is an inherent lack of resistance to the disease.

Accordingly, the patient is the third factor to be discussed, particularly as to why treatment sometimes fails to cure those with acute syphilis. It is well-known that certain patients are cured of syphilis by a few injections of the specific drugs. It is less commonly known, but nonetheless well-established, that some patients spontaneously rid themselves of the disease without therapeutic aid. Such patients have an active defensive mechanism,—a high resistance to the infection that was probably present before the disease was acquired and was not produced by it. Bruusgaard³ has shown that approximately thirty per cent of patients who acquired syphilis and were observed for fifteen or more years were spontaneously cured, and that an additional fourteen per cent had only a positive blood test to show. The serious sequelae of the disease, such as syphilis of the heart and large blood vessels and syphilis of the central nervous system, occur equally in four per cent of the cases. The report of Bruusgaard was not advanced as an argument against the treatment of syphilis, but was the first published report of a large group of patients with acute syphilis who were not treated but were adequately observed for fifteen years. The Co-operative Clinic Group's study also showed that although 60 per cent of the patients who were not treated became symptom-free 96 per cent of those who were adequately treated did likewise. This finding, when augmented by the need for treatment to prevent patients with early manifestations of the disease from infecting others, is sufficient reason why individuals with acute syphilis must be treated.

Latent syphilis is an interesting and a vital stage in the life cycle of the individual who has syphilis. Latent syphilis may be defined as that period in the course of the disease when there is a complete clinical absence of the signs and symptoms of syphilis. Latency may appear after the second year of the infection, and the infection may remain latent for the rest of the patient's life, on the other hand, latency may be the quiescent period just preceding the appearance of the serious manifestations of the disease. A diagnosis of latent syphilis may be made only after a careful clinical search has failed to reveal evidence of the disease on the skin, in the special senses, viscera or bones, or central nervous system, and only when the spinal fluid is found to be negative. The status of the Wassermann or flocculation tests is not essential to such

The mild reactions, in the order of frequency, consisted of gastrointestinal upsets, nitritoid reactions, slight skin eruptions, pruritus, and mild irritability of the kidney. The severe reactions consisted of jaundice, severe exfoliative dermatitis, ocular damage, blood dyscrasias, hepatitis, and encephalitis. Arsphenamine and neoarsphenamine had a similar incidence of such reactions, whereas the reactions to sulpharsphenamine and tryparsamide (ocular) showed a considerably higher incidence. Silver arsphenamine and bismarsen had lower incidences of reaction.

The bulk of these reactions appeared during the first course of treatment. Patients are encountered who show reactions to one type of arsphenamine but are able to complete treatment when another form of arsenic is administered, when the dosage is decreased, or when treatment is stopped for several months and then reinstituted. The mild reactions are not a contraindication to attempting further treatment, but, following the severe reactions, such as exfoliative dermatitis and hepatitis, the utmost caution must be exercised in administering further treatment of any type. Jaundice occurred in one per cent of the patients treated, while exfoliative dermatitis was noted in 0.7 per cent. The other reactions were all considerably

lower in incidence. The milder reactions are the more common, as in a total of 177,360 injections, mild reactions occurred in 12.6 per cent and severe reaction in 2.3 per cent. Death occurred in seventeen cases, eight patients dying of hemorrhagic encephalitis, two of toxic hepatitis, three of blood dyscrasia, and four of exfoliative dermatitis. In most of these cases the reaction leading to death appeared following a few injections of an arsenical, usually in cases of early syphilis.

With the therapeutic agents available now, both specific and nonspecific, we are able to cure a high percentage of patients with early syphilis, add years to the life of those with latent syphilis or those with the benign forms of syphilis, restore a portion of those to their jobs or to an earning capacity who were previously restrained in hospitals for the insane, and alleviate the symptoms of most of those who are in distress from involvement of the central nervous system. For those patients with syphilitic heart disease our efforts may relieve symptoms and add a few years to their lives if the process has not advanced too far. May I again stress the fact that the way in which the late complications of syphilis are to be avoided is by the intensive and adequate treatment of the disease during its acute or early phase.

received any previous treatment for syphilis. The blood Wassermann was positive in only seventy-nine per cent of the cases, and in fifty-six per cent of them a positive spinal fluid was detected.

Treatment of cardiovascular syphilis may ameliorate the symptoms and prolong the patient's life, depending on the severity of the involvement of the heart and blood vessels when treatment is begun. Increasing the life expectancy from three months to two years on the average is all that can be expected in these cases. The best treatment of cardiovascular syphilis is prophylactic, namely, the adequate treatment of early syphilis.

I have been studying the results in the prevention and treatment of neurosyphilis.⁷ These reports are not as yet completed, but the study has brought out several points which are worthy of emphasis. Asymptomatic neurosyphilis is that phase of the disease characterized by a positive spinal fluid test, but in which neither signs nor symptoms of involvement of the central nervous system are present. This is a significant type of neurosyphilis, not only because it is the forerunner of such complications in the nervous system as locomotor ataxia and general paresis, but also because it is a form of the disease that shows favorable response to treatment when such treatment is adequately applied.

About a third of those who acquire syphilis have a positive spinal fluid, usually during the first few years of the disease. In some of these cases the fluid becomes negative spontaneously or with but little treatment, in other cases the fluid becomes negative only after strenuous, intensive, and specialized forms of treatment, whereas in still other cases the spinal fluid remains positive in spite of treatment. It is in these last cases that the late types of syphilis of the central nervous system develop, namely, locomotor ataxia or general paresis.

It is fortunate that in the majority of cases of asymptomatic neurosyphilis the spinal fluid will revert to negative following the so-called routine treatment with arsphenamine and bismuth or mercury. In those cases which do not show a favorable response, augmenting the program of treatment with intraspinal injections or fever therapy may be necessary. By

the use of various combinations of treatment we are able in sixty-five per cent of the cases of asymptomatic neurosyphilis to produce and maintain negative spinal fluids. This is equivalent to saying that in sixty-five per cent of cases in which patients are destined to have syphilis of the nervous system, by efficient treatment these serious sequelae of the disease may be prevented. When these complications have become manifested in the nervous system and the patient is showing definite signs that the spinal cord or brain, or both, have become involved, the results of treatment are less encouraging.

I am sure most of you are familiar with the fact that malaria has now been used for the past twelve years in the treatment of certain types of neurosyphilis, and that electrical units which increase the body temperature have been developed to use in place of malaria therapy. From my own experience I believe that the results from malaria therapy are superior to those secured by the electric units, although both methods have certain advantages. It is significant that the majority of the reports in the medical literature of this country and Europe have revealed that about thirty per cent of the patients who had general paresis were able to return to work following the fever treatment. Prior to the use of fever therapy we had little hope of helping these patients. May I again emphasize the fact that the best treatment for neurosyphilis is the adequate and intensive treatment of early syphilis, for as a result the incidence of neurosyphilis will be held to a minimum.

I have purposely avoided mention of the results of treatment in congenital syphilis, syphilis of the special senses, and the benign forms of the disease, such as involvement of skin or bone, as these reports from the Cooperative Clinic Group's studies will not be available until next year.

Thus far I have included the good results of treatment, but before completing I wish to call your attention to some of the complications which accompany the treatment of syphilis. Cole⁸ studied the Cooperative Clinic Group's material and noted two types of reaction to arsphenamine: the mild and the severe.

puncture, a very helpful method of diagnosis which is often neglected. Procedures recommended in the literature are punctures in the left xiphocostal angle upward under the costal margin into the distended pericardial sac (Osler), and punctures through the third, fourth or fifth left, and fourth or fifth right interspaces, diagonally downward. However the most direct approach seems best, namely a puncture through the fourth or fifth left interspaces, three inches from the left border of the sternum. Either of these locations avoids the pleura. Care must be taken to avoid engaging the heart muscle, which can be accomplished by observing the free needle from time to time during its introduction. If it enters the heart muscle ever so little the cardiac impulse will be transmitted to the needle which will oscillate characteristically. No harm follows a slight engagement. Repeated punctures should not be made in presence of pus.

Pathology

Empyema of the pericardium usually starts as an acute pericarditis, fibrinous in nature, later becoming serous, then purulent, closely simulating changes leading up to empyema of the pleural cavity. The accumulation of pus increases in size more or less rapidly, distending the pericardium and embarrassing heart action. Many thick shreds of fibrin may form. The pericardium becomes thickened and is covered with a fibrinopurulent exudate. This pus has a peculiarly mucilaginous quality not seen in pus from the pleural cavity. It dries quickly and becomes very adherent.

In long-standing cases the inflammation may penetrate to the nearby pleura or mediastinum giving a pleuropericarditis or mediastinitis. This causes great thickening of the tissues about the heart so that they may surround it as an adherent blanket. If these adhesions are not gradually disintegrated by heart action and natural resolution they become permanent and we have a condition known as chronic constrictive pericarditis or Pick's disease, and a permanently disabled heart.

Treatment

Paracentesis of the pericardium has been mentioned as a diagnostic method. If pus is obtained the aspiration should be continued until as much fluid as possible has been removed. The relief afforded is in proportion to the amount removed, but unlike aspiration of the pleural cavity, the exit of the first one or two hundred cubic centimeters has a remarkably stimulating effect upon heart action.

As soon as possible after diagnosis is made the pericardium should be incised and thoroughly drained. This procedure offers practically the only chance of complete recovery. Unlike the pleura, the pericardium seems to be very tolerant to surgical procedures, does not seem to give rise to acutely painful sensations, and rarely gives rise to shock.

The condition of the patient will usually demand local or rectal anesthesia. Removal to the operating theatre may be impossible. The main precaution in the operation is to avoid opening the pleural cavity, for reasons self-evident. Either the fourth, fifth or sixth left costal cartilages should be resected beginning at the sternum, tying the internal mammary artery if severed and exposing the pericardium in the area free from pleura. In early cases the distended pericardium will be felt as a tense rounded sac, nonadherent to surrounding structures. The sac should be incised longitudinally at its most dependent portion. After evacuation of free pus the sac may be explored with the finger and adhesions broken. A saline irrigation may be used if desired. Drainage must be free and may be obtained either by insertion of gauze or rubber dam, but not in sufficient quantity to embarrass heart action. Rubber tubes should not be used. It will be found difficult to keep drains in place as heart action tends constantly to extrude them from the incision.

Shipley, who operated upon eleven cases successfully, uses open drainage by trans-sternal approach in children and the xiphocostal approach in adults followed by the Dakins technic. Other operators use negative pressure drainage, others gauze packs and rubber tubing. Effective drainage has been secured without foreign

EMPYEMA OF THE PERICARDIUM

Pyopericardium

DAVID H. HALLOCK, M D, F A C S, *Southampton*

Major, Med Res Corps, U S Army From the Surgical Service Southampton Hospital

Empyema of the pericardium is that phase of pericarditis which comprises the collection of a purulent exudate in the pericardial sac. The usual signs and symptoms of pericarditis with effusion are present and are familiar to the reader. It is very unusual for such an exudate to become purulent, but when this complication does occur, the case immediately becomes surgical, and on prompt surgical treatment the recovery of the patient depends. Pyopericardium is rarely a primary condition but usually occurs as a complication of some acute bacterial infection. In virulent cases pus may generate rapidly and death follow in from three to four days, almost before intervention is possible.

Etiology

The source of this infection is by way of the blood stream from some primary focus. Rarely it arises from direct extension from the pleura or mediastinum. Pneumonia is the primary disease responsible for by far the greatest number of cases. Occasionally it follows in the course of an acute purulent arthritis, also in tuberculosis, the frequency being in the order named. Scattered cases have been reported following acute rheumatic fever, scarlet fever, septic processes such as acute osteomyelitis, puerperal and intrathoracic infection, and also following cardiac infarction. Associated cardiac disease is present in many cases but with the exception possibly of septic cardiac infarction, has no part in the etiology. Tuberculosis of the pericardium may give huge collections of fluid, as much as four liters having been removed at one time from the pericardial sac. The fluid is often hemorrhagic as well as purulent. Tuberculous pericarditis is most apt to be found in advanced pulmonary or miliary cases and is frequently overlooked as a terminal infection.

Symptoms and Signs

The symptoms and signs of this condition are those of fluid in the pericardial sac. Precordial pain is not always a symptom. Usually distinctive symptoms are masked more or less completely by those of the primary disease, as occurs in pneumonia. Purulent pericarditis should be thought of in cases of pneumonia in robust adults where the heart shows signs of beginning failure before the crisis, or after the crisis, when there is prolonged convalescence with persistent fever. If the collection of fluid is large the cardiac impulse disappears, cardiac and aortic dulness become much extended, heart sounds become very weak and rapid, and the pulse may be reduced to a slight flutter. In children and young adults bulging of the chest may be observed. This sign is rare in adults due to costal rigidity. The x-ray picture is distinctive (Fig 3), giving the wide shadow typical of a distended pericardium.

Whenever the amount of thickening and induration of the pericardium and accumulation of pus occurs to the extent that the heart action is markedly embarrassed, we get the series of symptoms and signs known as "inflow stasis." The heart, restrained by its surroundings, alternates between systole and slightly relaxed systole. Full diastole does not take place. The right and left hearts have no opportunity to fill with blood before the succeeding systole, and thus arises a venous stasis of the entire body. This stasis soon manifests itself by a massive anasarca with great enlargement of the liver. If unrelieved, death results from circulatory stasis.

Diagnosis

Pyopericardium can be differentiated from simple effusion only by exploratory

cures and one (8%) improved, using the Delorme operation. Venus reports seventeen resections in which series all cases were improved. He states that a complete cure cannot be expected. J. E. Summers reports seventy-five per cent improvement in thirty-eight chronic cases reported in the literature. Smith and Willins from one hundred forty-four cases of chronic adherent pericarditis report sixteen cases of proved calcification of the pericardium following infection, fifteen cases being proved by autopsy, one in life by x-ray. Twelve were males and three females. Death was from heart failure. Calcification is frequent in tuberculous cases.

Thus we see that the immediate as well as the late prognosis in purulent pericarditis is serious. Immediate drainage is imperative no matter how sick the patient may be, and offers the only hope. The majority of cases die during the acute phase, a small number survive unoperated and become chronic invalids. In these few the radical resection of the thickened adherent pericardium may help a small number, but complete cure is not to be expected.

Case Report

T. K., aged twenty-one, occupation, farm laborer, was admitted Sept. 25, 1935.

Chief complaint Pain in the chest and cough.

Family history Irrelevant.

Past history Influenza five years ago.

Present illness "Caught cold" one week before admission. Lay on ground under tree for some hours while sick. Became worse two days before admission and was put to bed suffering with shortness of breath, cough, and fever.

Physical examination Very well-nourished and developed young man lying in bed in acute respiratory distress, suffering with pain in the left chest. T 104° P 130, R 28. Coughs at intervals and expectorates a dark sputum. Head. Tongue coated. Otherwise normal. *Chest* Marked dullness over lower left chest posteriorly, extending to left front where less marked. Vocal fremitus and resonance are increased over this area. Prolonged expiration. bronchial breathing, and many moist rales are heard over lower left lobe behind and to less extent in front. A few moist rales are heard over the lower right lobe behind. No dullness. Heart sounds are of good

quality but rapid. No murmurs are heard. Cardiac dullness percusses to three cm beyond right border of sternum, heart being definitely displaced to right. On the left cardiac dullness merges with that of

Fig 3 *Twelfth day* Consolidation as in Fig 2. Heart shadow very markedly enlarged both to right and left. Aortic shadow twice normal width.

Fig 4 *Seventeenth day* Shadow of left lower lobe mottled in appearance. Cardiac shadow reduced almost one-half in size and surrounded by halo of haziness. Aortic shadow much smaller.

Fig. 1

Fig. 2. *Third day.* Portable film of chest shows shadow of consolidation of lower lobe of left lung. Heart shadow displaced to right and enlarged both to right and left.

substances simply by posture, such as lying on the left side.

Unfortunately the condition of many patients is such that the least extensive surgical procedure which will secure relief is imperative. This is illustrated in the case here reported. In such cases we must be satisfied with simple intercostal incision and drainage with a carti-

lage resection later if necessary, when the patient improves sufficiently. Postural drainage should be especially useful in these cases. In early cases drainage may not persist beyond ten days and resection be unnecessary.

The use of the Carrel-Dakin technic is not advocated because not only is it unnecessary but also because the tubes and solution have been shown by Beck to be very successful in the production of chronic adhesive pericarditis experimentally in dogs the adhesions which formed being described as "strangulating" in type.

The use of air-tight negative pressure method of drainage is not advocated because it necessitates the presence of tubes within the pericardium, interferes with free drainage, and prolongs convalescence by favoring cardiac adhesions. A heart functioning well enough to support life while compressed in a sac of pus will find little embarrassment from operating at atmospheric pressure. With the patient at rest there is no inflow and outflow of air through the pericardial opening during respiration as through a thorocotomy for pleural empyema. Only during violent coughing does this rush of air take place. It is easily controlled by the dressing in place which acts as a negative pressure valve if such is needed.

Prognosis

The prognosis in such cases is favorable only if pleuromediastinal changes have not taken place. Venus cites three hundred acute cases, one hundred ninety-seven of which were operated upon; seventy-two (40.5%) were cured, and six (3.1%) were improved. Bogard cites one hundred seventy-one cases reported up to May 1931 with seventy-seven early deaths and ninety-four recoveries (45% mortality). Porter cites fifty-one cases incised with twenty recoveries and thirty-one deaths (60% mortality).

If pleura or mediastinum become involved we later have chronic constrictive pericarditis which can be cured only by pericardial decortication (Brauer's operation). Otherwise the patient remains a hopeless invalid. White cites twelve resections of the chronically thickened pericardial tissues with six (50%) complete

cures and one (8%) improved, using the Delorme operation. Venus reports seventeen resections in which series all cases were improved. He states that a complete cure cannot be expected. J. E. Summers reports seventy-five per cent improvement in thirty-eight chronic cases reported in the literature. Smith and Willins from one hundred forty-four cases of chronic adherent pericarditis report sixteen cases of proved calcification of the pericardium following infection, fifteen cases being proved by autopsy, one in life by x-ray. Twelve were males and three females. Death was from heart failure. Calcification is frequent in tuberculous cases.

Thus we see that the immediate as well as the late prognosis in purulent pericarditis is serious. Immediate drainage is imperative no matter how sick the patient may be, and offers the only hope. The majority of cases die during the acute phase, a small number survive unoperated and become chronic invalids. In these few the radical resection of the thickened adherent pericardium may help a small number, but complete cure is not to be expected.

the pulmonary lesion. *Abdomen* Distended and tympanic to percussion. Markedly tender along both costal margins. Liver, kidneys, and spleen not felt. No fluid wave. *Extremities* No edema.

Diagnosis Acute lobar pneumonia, left lower lobe. *Clinical pathology*

Urmalysis Albumin—3 plus, hyaline and granular casts, few leukocytes. Albumin and leukocytes persisted throughout. Casts disappeared after first specimen.

Blood count Hgb eighty-five per cent fell to seventy-eight per cent at lowest. RBC 4,860,000 to 3,990,000. WBC 40,450 to 14,550. PMN ninety-two per cent to eighty-two per cent. Lymph six per cent. Myeloc, two per cent.

Sputum Type I pneumococcus (Sabin-Neufeld method).

Pericardial fluid Yellow, purulent in appearance. *Smear* Many pus cells and Gram positive diplococci. *Culture* Gram positive, lancet-shaped diplococci, pneumococcus, type I by Sabin-Neufeld method.

Blood Chemistry NPN twenty mg per 100 cc blood. Creatinin 17 mg. Wassermann Negative.

Course

Following intravenous administration of

type I antipneumococcus serum the temperature gradually fell from 105 to 101° F on the thirteenth day. Aspiration of the left chest twice gave negative results. After the thirteenth day the temperature again rose. X-ray on the twelfth day showed fluid in the pericardial sac. Aspiration on the pericardium on the fifteenth day gave 100 cc of pus. On the seventeenth day the pericardium was incised and about one liter of purulent fluid was evacuated. Profuse daily drainage was aided by the fact that the patient elected to sleep on his left side. Nine days after incision the temperature reached normal. Two days thereafter (28th day) the temperature rose to 104 degrees and a general anasarca began to develop. On the thirty-fourth day aspiration of the right chest gave 250 cc of clear straw colored fluid. The abdomen became markedly distended and gave a very distinct fluid wave. The liver soon reached twelve cm below the right costal margin and became very tender and painful. The face and hands were very edematous. By fluid restriction, ammonium chloride forty-five grams by mouth daily and two cc of salyrgan (mer salyl) intravenously every other day, the anasarca gradually subsided without further paracentesis. By the forty-eighth day the liver edge had disappeared behind the

Fig 6 *Sixty-first day* Heart shadow normal in size, surrounded by area of haziness. Aortic shadow normal. Resolution of lower left lung practically complete. No fluid in pleural cavity.

costal margin and very little fluid remained in chest or abdomen. Temperature was 100, pulse 110 to 94 and regular. Patient was allowed up in chair without dyspnea or other cardiac embarrassment, and discharged on November 29 (65th day) able to be up and around and care for himself. Physical signs were negative, incision completely healed. Radiograph showed cardiac shadow of normal size.

Operation

Because of critical condition patient was not removed to operating room. Iodine and alcohol preparation over precordium. Fourth left costal interspace infiltrated with two per cent novocain to the pericardium. Aspirating needle inserted and pus obtained. Needle was left *in situ*. A longitudinal incision three inches long was then made in the fourth interspace beginning three inches from the left sternal border, and deepened through the intercostal muscles. The chest was then entered with the finger which felt the pericardium as a tense distended sac, non-adherent to surrounding tissues. The most dependent part of the sac was incised by a longitudinal incision, the blade of the scalpel inclining away from the heart. About one liter of moderately thick yellow pus was evacuated. There was no shock and very little pain. There was no rush of air backward and forward into the

cavity except when the patient coughed violently. The patient was then turned on the left side to favor drainage and a six-inch rubber dam drain inserted into the pericardial sac and anchored to the edge of the incision. The patient was immediately relieved by the procedure.

Conclusion

This case is reported because of the rarity of the condition and also because it demonstrates most of the symptoms and signs that might be met with in a similar case, including the state of "in-flow stasis." This phenomenon occurred shortly after drainage was established. The patient began to accumulate fluid throughout the body, in abdomen, chest, and extremities. The liver became huge and very tender, the abdomen was distended with several gallons of transudate. Fortunately it was possible to control this accumulation by medical means. As much as five liters of urine was passed in twenty-four hours on a one-liter fluid intake. After two weeks of anasarca the fluid gradually ceased to collect and one week later the liver edge had disappeared above the costal margin.

DO YOU KNOW?

The first bifocal eyeglasses were invented by Benjamin Franklin.

Homicides and suicides are decreasing with the improvement of economic conditions, but fatal accidents are on the increase.

The first ambulance service was started in June 1869, by Bellevue Hospital, New York City, under the direction of Dr. Edward B. Dalton.

Athlete's heart is supposed to be an ailment resulting from active exercise. There is no evidence that a healthy heart is harmed by athletic activities.

Good posture is a sign of self-respect, besides being conducive to health.

Each of the billions of red blood-cells in the body contains, besides life-giving oxygen, a charge of electricity. Two scientists of the Biological Laboratory at Cold Springs Harbor, Long Island, have measured this charge. The electricity of the blood-cells of a full-grown man they found, would light a twenty-five watt bulb for five minutes.

Shakespeare said: "They are as sick as surfeit with too much as they that starve with nothing."—*Excerpts from the Bulletin issued by the Bureau of Public Relations of the Medical Society of the State of New York*

MUSCLE INJURIES

CLIFTON W HENSON, M D , *New York City*

Asst Attending Surgeon Broad Street Hospital

This paper is limited to disorders of the muscular system following trauma. Disturbances of the muscle associated with injuries of other structures, such as bones or joints, are not discussed as it is thought they are better understood when described with the pathology influencing them.

Etiology of Muscular Injuries

Muscles may be injured by direct trauma or indirect violence. The direct trauma may be due to a blow or a laceration caused either by a sharp instrument or a projectile. The following case is reported as typical of this condition.

Man fell a distance of five feet from a ladder landing flat on his back. Experienced pain over his entire back below the scapula. This pain continued and later became localized in both lumbar regions. X-ray plates of the back revealed no evidence of bony injury. The pain was aggravated by bending and more so by attempting to lift objects.

Examination The patient indicated the region on each side of the spinal column extending from the twelfth rib to the iliac crest as the part injured. Palpation of these parts revealed small tender areas of induration scattered throughout the erector spinae muscle groups, and many brownish discolorations of the skin. The muscles were spastic. Motions of the back were limited.

Diagnosis Contusions of the back muscles with focal areas of cellular injury and induration.

Treatment Rest, immobilization of the back by means of adhesive. Applications of heat infrared being used for the first two weeks, then diathermy. Massage begun at the end of the first two weeks and gradually intensified. Following six weeks of this treatment, gradually increasing exercises initiated.

Disability Returned to work at the end of two months, and heavy work one month later.

Permanent defect When this patient was last seen, he complained of dull spasms of pain in the back during damp weather and

dull ache following prolonged exercise. Examination of this area demonstrated thickened areas within the substance of the muscle, some being tender. There was no defect in motion of the back. The attacks of pain will probably continue a year or more.

Indirect Injury

Indirect injury is brought about by a contraction of the muscle under unusual circumstances, as follows.

1 CONTINUED USE AFTER FATIGUE

Patient stated that he was employed as handy man in a building, his regular occupation being that of a painter. He was placed at work requiring no physical effort for a period of nine months and then started painting ceilings. He experienced pain in the right arm after the first week, the pain being a constant ache aggravated by exercise and of greater intensity at the end of the day. This pain gradually increased. At the end of the third week the arm became weak and the man was unable to accomplish the proper amount of work. The following week he was unable to continue working as he was unable to hold the right arm over his head for more than a few minutes.

Examination Flabbiness of the muscle about the right shoulder, these muscles having less tone than those about the opposite shoulder. There was no tenderness, no muscle atrophy, and no defect in motion but the man showed fine fibrillations in the muscles about the right shoulder when the right arm was elevated to the vertical for a few minutes.

Diagnosis Fatigue of muscle about right shoulder.

Treatment Absolute rest for a period of one month. The man was allowed to take his vacation during this period. Light work was then begun requiring no lifting or elevation of the arm. The man was encouraged, as he was afraid that the arm would not return to normal. Massage was administered three times weekly during the period of light work. At the end of one month, the man was able to undertake heavy work with no symptoms.

Disability Total one month, and partial one month.

Permanent defect None

2 SEVERE USAGE AFTER LONG PERIOD OF IDLENESS

Man stated that after a period of inactivity for several months he was placed at the task of lifting heavy bags throughout the entire working day. He experienced pain in the abdomen and back following this and two days later, during which time the pain and soreness had gradually increased. He was unable to rise from a prone position unassisted. He thought that he had been ruptured and was told by a physician that he had strained his abdominal muscles.

Examination Patient indicated the entire back from the tenth rib to the iliac crests, and the entire abdomen as the parts in which he experienced pain. As he indicated this area his hands passed from the lumbar spine obliquely forward and inferiorly, in the course of direction of the external oblique muscle. Palpation of this area revealed no masses, but tenderness was elicited upon deep pressure.

Treatment Infrared radiation for the first week, with addition of massage for the following two weeks.

Disability Three weeks

Permanent defect No symptoms at the end of three weeks

* CONTRACTION OF OR PULL UPON DISEASED MUSCLE, DUE TO TOXEMIA

Patient leaned forward and picked up a drawer and felt a sudden sharp pain in the right posterior chest. Pain gradually extended to the right side of the neck. Home remedies including heat from an electric bulb produced no results so a physician was consulted three days after the accident, the patient complaining of pain in the posterior right chest, right side of back, and wry neck with head tilted toward right side.

Examination General appearance, slender young man of asthenic appearance. Tired expression.

Tenderness and slight muscle spasm of right interscapular region. Rigidity of right sternocleidomastoid muscle with shortening, causing characteristic tilt of head toward right side.

Diagnosis Auto-intoxication, Strain of right rhomboideus and right sternocleidomastoid muscle.

Treatment Detoxication, baking, and later massage. Man was placed on a diet of fruit and vegetables with daily saline catharsis and infrared radiation of affected areas every second day. Upon appearance for third radiation treatment, patient had no symptoms and all signs had disappeared.

Disability Partial five days

Permanent defect None

4 SUDDEN ACTION IN UNUSUAL MANNER DURING AN EMERGENCY REQUIRING MORE FORCE THAN THE MUSCLE IS CAPABLE OF EXERTING

Patient attempted to throw a heavy case towards his left side. His helper stepped in the way and to avoid hitting him with the case, the man arrested the motion suddenly. He experienced sharp stabbing pain in both interscapular regions, aggravated by motions.

Examination Induration of muscles extending from spinal column to the medial borders of the scapulae. Muscle spasm and tenderness present throughout both interscapular regions. Pain experience upon pulling against resistance.

Diagnosis Strain of interscapular muscle groups.

Treatment Adhesive strapping extending transversely, pulling scapulae toward each other and obliquely over the shoulder to prevent upward movement of the scapulae. Improvement was noted at the end of one week and the patient insisted upon returning to work against advice. He discontinued work one week later and examination revealed muscle spasm, induration, and tenderness of the muscles of the lower one-half of the left interscapular region and the upper one-half of the right. Infrared radiation and massage was then begun, strapping being applied between treatments. Light exercise was begun at the beginning of the fifth week, and the man returned to work the following week.

Disability Six weeks. Probably prolonged by early attempt to work.

Permanent defect None

5 UNUSUALLY STRONG RESISTANCE TO CONTRACTION

Man assisting another man lift a garbage pail which he states was an unusually heavy one. They lifted it quickly and threw it over. He twisted his back in throwing the pail and experienced excruciating pain in the left side of the upper back. This severe pain continued and the man was unable to move his back in any direction.

Examination X-ray pictures revealed no bony injury. Patient indicated the left interscapular region as the part injured. Palpation of this region revealed a tender mass about four inches in diameter within the lower one-third of the left interscapular region. This mass was definitely within the muscle tissue. It was roughly spherical and projected three-quarters of an inch

above the surrounding tissues. Motion of the back was limited in all directions and caused pain in this mass.

Diagnosis Rupture of the fibers of the left rhomboideus muscle.

Treatment Back strapped transversely to pull scapulae together, and patient remained in bed for two weeks. Pain diminished but the patient was still unable to bend his back. After this rest period, patient was treated by means of diathermy and later the addition of massage. Duration of treatment was twelve weeks.

Disability Light work begun twelve weeks after injury. Heavy work two weeks later.

Permanent defect When this man was last examined (June 19, 1936—fifteen weeks after injury) he complained of a dull pain in the left interscapular region after hard work. Examination revealed thickening within the muscle tissues.

Prognosis Permanent thickening within the muscle and occasional pain for a year or more.

6 TEARING OF THE FIBERS DURING USE, DUE TO DEGENERATION AS RESULT OF AGE

While pushing a loaded hand car up an incline with left foot in front of body and right foot behind, man, aged sixty-two, experienced a sudden shooting pain in the calf of the right leg. Pain persisted and was so aggravated by walking that he was unable to continue working. He visited a physician who advised the application of hot towels. Two days later the swelling was considerable, so the man applied iodine without consulting a physician and a large blister resulted.

Examination Blister about one inch in diameter in center of calf of right leg. Purplish discoloration of skin over posterior surface of calf around blister throughout an area approximately three inches in diameter. Area swollen and tender, with a mass palpable just superior to the blister, being about one inch in diameter. Pain experienced in this discolored area with maximum intensity within the mass on flexion and extension of the ankle.

Diagnosis Rupture of fiber of right gastrocnemius muscle. Second degree chemical burn due to application of iodine.

Treatment Removal of skin from blister and application of antiseptic bandage. Application of diathermy, plates being placed above and below blister. Absolute rest. Later, massage following diathermy.

Disability Three weeks.

Permanent defect When last examined,

(June 15, 1936—six weeks after injury) he complained of the occurrence of pain in the center of the right calf following heavy work, a small mass located at the approximate center of the calf was tender. Occasional attacks of pain and tenderness will probably continue for a year or more.

These accidents produce acute disturbances of muscle function. Chronic disturbances sometimes follow, due to the development of fibrosis or calcification within the muscle substance. Fibrosis results from the healing of muscular defects or the organization of blood, but the factors responsible for the production of calcification are not altogether understood.

Calcification occasionally takes place within a fibrotic area following uncomplicated muscle injury, but true myositis ossificans usually develops only following complicated injuries, particularly involving the joints. This condition is, therefore, not considered in this communication.¹

Pathology

The pathology following muscular injuries resulting from direct or indirect violence is similar, the particular point of difference being distribution. The changes produced by direct trauma are usually limited to the portion struck or lacerated, whereas, when injury is due to muscle strain the pathology often extends throughout the muscle involved. This is not true if the muscle is torn, as the tear releases the tension on the other parts of the muscle, the pathology being practically limited to the part torn.

The immediate pathology may be divided into three types, which seldom occur alone and are often in combination. They are (1) exudation, (2) tissue severance and necrosis, and (3) hemorrhage.

In addition, certain physicochemical changes are supposed to take place in muscular fatigue which are not completely understood, but resemble those found in rigor mortis.²

Following muscular injury insufficient to cause muscle cell necrosis but sufficient to injure cell membranes, there is an accumulation of tissue fluids, lymph, and serum in the cellular space, causing an increase in tension and bulk. This causes pain by pressure on nerves which is in

eased by muscular contraction resulting further increase in tension³

When muscle cells are torn or killed, the pathology described is complicated by the addition of defects in the continuity of muscle tissue of varying sizes and many free or semi-attached particles of devitalized muscle fibers which may be considered as particles of foreign protein

Hemorrhage may be of two varieties, oozing from raw surfaces, or bleeding from a lacerated vessel

The effusion described in the first type of pathology ceases upon sufficient increase of the intercellular pressure. The cell membranes heal in approximately one week and the fluids are gradually absorbed—this process is usually completed within ten days to two weeks

Hemorrhage always occurs when muscles are lacerated. The resulting pathology depends upon the degree of bleeding, type, location, and the influence of the surrounding structures. Oozing from raw surfaces produces blood mixed with tissue fluids, a thin serosanguinous solution. If this takes place within the muscle, the result is similar to the first type of pathology described. If, however, this takes place on the surface and the surrounding structures are loose and capable of distension, the fluid accumulates in a pool, its limits being defined by fascial attachments and its size dependent upon the duration of the bleeding which is to some extent controlled by the resistance of the tissues. The following case report is an illustration of this condition

A case of canned goods fell on the left thigh. Patient experienced pain for a few minutes but experienced no further pain until nine days later. Patient then noticed a swelling on the anterior surface of the left thigh, he also experienced a sensation of stiffness in the left thigh but no pain or tenderness. Five days later, he reported for examination on account of persistence of this swelling

Examination Oval mass on the anterior surface of the left thigh, its long diameter vertical being ten inches in length, five inches in width, and projecting above the surface of the surrounding skin approximately two inches. Mass soft and fluctuant but not tense. Bluish discoloration present in the center of the lower one-third of the mass and on the lateral surface of the thigh

No tenderness or muscle spasm present at any point on the thigh or knee, no pain experienced upon moving these parts

Diagnosis Cyst on anterior surface containing fluid, most probably serum

Treatment Large needle inserted after anesthetization of skin by means of wheal of novocain. Approximately one pint of serum extracted. Pressure bandage applied and patient was allowed to continue his usual occupation. About one-sixth the original quantity of fluid reaccumulated. This was gradually absorbed without further treatment and one month after injury, examination revealed no swelling or other evidence of pathology upon the left thigh

Disability None

Permanent defect None

True hemorrhage takes place if the vessel is ruptured. If this occurs within the muscle substance the subsequent accumulation of blood is smaller than that resulting when the hemorrhage is relatively superficial but the mass is larger than that caused by oozing, as the pressure of the blood in the arteries and arterioles is greater than that of the muscle tissue and is therefore capable of pushing the fibers aside

Therefore, vessel rupture within the muscle but beneath an unbroken capsule may cause blood to infiltrate between the entire muscle and capsule and slowly penetrate through the muscle tissue. If the pressure is sufficient, this may result in considerable necrosis of cells and finally produce a sac surrounded by the fibrous capsule and containing blood and muscle tissue in varying degrees of vitality

If this capsule is torn and hemorrhage takes place the final location of the hematoma is dependent upon the distribution of the surrounding fascia, propulsive force of muscular activity, and gravity

Accumulations of serosanguinous fluids are usually absorbed, but occasionally, if the mass is large and the surrounding tissues relatively impervious, absorption does not take place and a cyst is formed

A hematoma may be either absorbed, liquified or organized. The smaller accumulations are more apt to be absorbed. When liquifaction takes place, a cyst is formed and fibrous tissue organization forms a hard mass⁴. This is infrequently infiltrated with lime salts

Symptoms and Signs

The usual signs following tissue injury are swelling, ecchymosis, induration, tenderness, heat, and limitation of motion. Any or all of these may be present. In addition, muscle spasms occur in the form of fibrillation, strong clonic contraction or continuous tonic contractions producing rigidity. Later, stiffness or lack of pliability occurs due to fibrosis.

Contusion and rupture of muscle fibers produce similar signs. In each instance a localized tender mass forms within the muscle. This tender lump has been given the lay name of "charley horse." Ecchymosis always follows contusion but is found after muscle rupture only when the affected muscle is superficial. If the entire muscle is torn across, two lumps are caused, with a depression between them.

The particular signs of muscle strain are muscle spasm, tenderness, increase of pain when the affected muscle or groups of muscles are used, and limitation of function.

When the strain is due to overexertion of untrained muscles, large groups of muscles are usually affected, and the signs are less intense than when severe strain has been produced by excessive contraction. If toxemia is a factor in the condition of the muscle, pain is experienced upon stretching the muscle, this pain being particularly severe at the tendinous insertions.⁵

Muscles that have been used for a prolonged period after fatigue produce different signs. Pain and tenderness may or may not be present but the muscle spasm is not present, the muscle being unduly flaccid and retarded in action.

The immediate evidence of hematoma formation is the presence of a smooth mass of uniform density. This may vary in size and consistency being soft and fluctuant due to the accumulation of serosanguinous material in lax tissues, but hard and tense if caused by actual hemorrhage into an underlying cavity. Ecchymosis may or may not be present. These formations may appear immediately or several days after accident, and if delayed in appearance may occur at some distance from the point of injury⁶ due to gravity or muscle action.

Permanent muscle injury is detected by the palpation of single or multiple hard masses within the tissue or a sensation of stiffness which varies from a reduction in flexibility of a part or all of the muscle, to a board-like condition with complete loss of pliability.

Diagnosis

Contusion and laceration of muscle are easily recognized by the history and evidence of trauma.

Muscle strain resulting from strenuous usage after a period of comparatively little usage is differentiated from that due to excessive contraction by attention to the difference in the degree of symptoms and signs, those following the last condition being more severe and continuing for a longer period of time.

Muscle strain complicated by toxemia may be diagnosed by a consideration of the general condition of the patient, usually of an asthenic toxic appearance and the characteristic signs, namely, aggravation of pain upon stretching the muscle rather than upon contraction of it, as in other types of strain. Furthermore, the pain generated by this movement is at or about the tendinous insertions of the muscle.

Rupture of muscle fiber is characterized by nodular, tender masses within the muscle tissue and hematoma formation by the occurrence of smooth tender masses, either within or without the muscle tissue.

Fatigued muscle presents an entirely different syndrome from any described, namely, weakness, retarded reaction, and increased pliability, whereas, fibrous or calcareous formation within the muscle tissue causes weakness but decreased pliability and varying degrees of stiffness. Diagnosis is not, therefore, difficult.

Treatment

Following injury, muscle tissue undergoes three periods of change—exudation, absorption, and regeneration.

Although these are not sharply defined for practical purposes, the duration of the first period may be considered seventy-two hours,³ the *second*, two weeks and the *third*, the interval between the end of the second and the return to normal.

the maximum point of improvement. The first two periods vary according to the severity of the injury and the second period also varies directly with the size of the swelling or mass.

Treatment consists of measures to reduce exudation, increase absorption, and restore normal function. Cold compresses are useful during the first period and absolute rest is particularly important.

Heat, in the form of infrared radiation or diathermy, massage, and function promote absorption. Infrared radiation appears to produce better results in muscle injury, diathermy in hematoma formation, and an electric pad or hot water bag may be used to either supplement the other forms of heat or alone if the others are not available.

If toxemia is a factor, absorption of noxious substances in the muscle is accompanied by elimination and change of diet. Albee² recommends a series of medicated colonic lavages. In tenacious cases these might be useful, but in the average case, strenuous and repeated saline catharsis will suffice. The diet is restricted to vegetables and fruits until all symptoms disappear. The important point is the recognition of the toxic factor, as in many cases the results of treatment are gratifying and rapid.

Massage encourages absorption by spreading the mass, thereby increasing the surface susceptible to absorption and stimulating the flow of blood and the interchange of fluids. If, however, it be too vigorous, tender, recently injured cells may be damaged resulting in exudation instead of absorption. The guide is sensation. Massage of acute injuries should be soothing and should be kept below the intensity necessary to produce discomfort. Massage should never begin until two weeks after injury, and then gently.

If there be no rupture of muscle fibers, no mass or hematoma formation, function without resistance or strain upon the muscle injured is beneficial as the contractions promote the circulation of blood and therefore absorption. If masses are present, absolute rest should be insisted upon until healing has taken place around the area, making further hemorrhage impossible. Two weeks is usually required for this process and the clinical signs of

its accomplishment are disappearance of heat, reduction of tenderness, and signs of stability.

The rehabilitation of muscle tissue is promoted by massage and exercise. This requires judgment in each case, the objectives being increasing intensity of both below the threshold at which discomfort is produced.

In the average case three periods of treatment a week are sufficient, heat applications requiring twenty minutes and massage ten to fifteen minutes. It is probable that daily treatments will shorten the disability and reduce the degree of permanent changes following severe injuries.

In the case of minor muscle injuries with no tissue necrosis, treatment is not a necessity. It affords relief to the patient and shortens the duration of symptoms but the condition will be cured by natural processes regardless of treatment.

However, if serious muscle injury with accumulation of necrotic tissue or blood are allowed to continue without treatment, the chances of fibrosis with subsequent permanent stiffness are greatly increased. The following is an example of this condition.

On March 28, 1935, patient slipped while standing on rear spare tire falling backward and striking his back against the bumper of a car standing behind. He visited a physician in August on account of continuance of back pain and was told that he had bruised his back but no treatment was recommended. Pain over the left side of the back continued and increased. Patient continued working, but on account of continued increasing pain consulted a physician again in March 1936. This physician found no pathology. Being dissatisfied and still experiencing dull, aching, constant pain aggravated by exercise, located on the left side of the back, the man visited a hospital where x-ray examination was made. He was told at the hospital that he had a crushed vertebra. He then visited a chiropractor upon the advice of friends and began regular treatment in April. The pain at this time had extended to the back of the left thigh and leg. It improved under treatment and by June 15, the pain in the thigh and the leg had disappeared and the pain in the back was less intense.

Examination. Stiffness of muscle of left side of back over an area extending from the iliac crest to the tenth rib and about

Symptoms and Signs

The usual signs following tissue injury are swelling, ecchymosis, induration, tenderness, heat, and limitation of motion. Any or all of these may be present. In addition, muscle spasms occur in the form of fibrillation, strong clonic contraction or continuous tonic contractions producing rigidity. Later, stiffness or lack of pliability occurs due to fibrosis.

FEVER THERAPY IN PSYCHIATRIC PRACTICE

P R VESSIE M D, *Briarcliff Manor*

Following the general interest in fever therapy we have treated a number of patients with stimulative fevers at Stony Lodge. These treatments, covering a period beginning in the Fall of 1933, were administered to a selected group of twenty out of one hundred and twenty-five admissions.

At no time was this form of therapy employed with the expectation that it might provide a radical cure. Hence, its application was mostly confined to those patients manifesting disturbed states which did not respond to ordinary measures. It was hoped that the sulphur treatment would serve to divert the patients from their intense psychological preoccupation by introducing an element of bodily concern.

To induce such fevers we used a one per cent preparation of sulphur in oily suspension. Usually from ten to twelve injections completed a course of treatment, the injections being given deep in the gluteus every other day before noon. The first injection consisted of one c.c. of the sulphur suspension, the second two c.c., the third and maximum dose was three c.c.

Compared with malaria and typhoid vaccine therapy the fever induced by sulphur can be easily controlled and the danger of hyperpyrexia is practically negligible. In all the patients under sulphur treatment we aimed to keep the fever temperature within the range of from 102 to 104°F, thus avoiding complications such as collapse and marked loss of weight. Rectal temperature was taken frequently in order to ascertain the highest point of fever elevation.

In some instances before the maximum fever temperature was reached sharp chills were observed. The fever temperatures appeared usually after ten or twelve hours, and, as a rule, subsided abruptly on the following morning. Respiration rate remained nearly normal. Heart rate never exceeded 120 beats per minute. Perspira-

tion was a common symptom. Secondary anemias did not develop from the small doses of sulphur. When there was no fever, the patients were permitted to be up and dressed and outdoors if the weather permitted. Graphic charts were kept of the temperature curves and pulse rate.

Schizophrenia

In the treatment of six male and two female schizophrenics it was found that a fever series covering twenty-one days brought no result which approached a recovery in any individual instance. But it was learned through repeated experiences that whenever such patients showed signs of catatonic excitement, the sulphur, if injected early, would frequently abort an oncoming episode. In some instances one injection would suffice; in others two or three injections were necessary to disperse the excitement. For one thing the fever created a condition which made these restless, disturbed patients disposed to remain in bed. Also the temporary local pain at the site of the injection undoubtedly diverted the patient from an exclusive preoccupation with his mental state.

It was because of this response to sulphur that it was used as a routine measure in typical schizophrenic situations and after repeated experiences we became confident that the sulphur treatment was a distinct aid in curbing excitement episodes which otherwise may have extended over a period of weeks.

There was, however, no evidence that the basic psychosis had in any way been altered. The absence of troublesome manifestations in behavior over a period of months may have given the impression of mental improvement. Nevertheless, there was a persistence of delusions and hallucinations, mental peculiarities, mannerisms, and other indications of deterioration.

Psychoneuroses

A man, aged forty-four, with a psychogenic neurasthenia of one year's duration demanded in a most aggressive manner the application of the latest treatment in psychia-

From the Clinical Service of Stony Lodge, Ossining

four inches lateral to the spinal column. Muscle thicker than those of the opposite side. Tender and resistant to touch. Examination of left thigh and leg, negative.

X-ray examination revealed depression of the left side of the fourth lumbar vertebra causing angulation of the spine above it and towards the left side about twenty degrees. No change in consistency or density of the body of the vertebra, demonstrating the fact that it had not been crushed.

Diagnosis Chronic fibrosis—myofascitis—of erector muscle of left side of back as result of severe contusion.

Treatment Heat and vigorous massage until maximum point of improvement is reached.

Prognosis Elimination of constant pain within a few months. Continuation of periodic attacks of pain initiated by atmospheric changes, emotional crises, and exercise.

The pathology of fatigued muscle is different and therefore the treatment required is different. The muscle cells have reduced vitality and reactivity, and need rest and food. This may be provided in a combination of rest of the organism and the application of heat and massage to stimulate the circulation of blood and interchange of fluids ordinarily produced by voluntary muscle contraction. When muscle tone begins to return, usually within two to four weeks, active motions should be started and gradually increased as the strength of the muscle increases.

Course and Disability

The period of disability and the percentage of possibility of permanent changes varies directly with the severity of the injury and the amount of muscle tissue involved. The average duration of disability is two weeks, the maximum three months.

The prolonged periods of disability usually follow falls of a considerable distance, the body landing prone or supine and consequently injuring large amounts of muscle tissue. Disability may be considered at an end when use of the muscle in its usual manner in no way aggravates

the symptoms and signs. The table below indicates the limits of disability to be expected following the various types of muscle injury.

Laceration	2 to 6 weeks
Contusion	0 to 6 weeks
Strain from overexertion	0 to 2 weeks
Strain from excessive contraction	1 to 6 weeks
Strain of the muscle	1 to 6 weeks
Muscle fatigue	1 to 6 weeks
Incomplete muscle rupture	2 to 8 weeks
Complete muscle rupture	3 months following operation

Hematoma formation does not cause disability, it is usually associated however with severe muscle injury. Another factor to be considered as influencing disability is the type of work required by the patient's occupation.

Incomplete muscle tear may be treated conservatively in the manner outlined, but complete rupture necessitates open operation and suture.

Permanent Defect

Permanent changes occur in a small percentage of muscle injuries. The percentage is reduced by active treatment. The defects occasionally expected are stiffness or weakness of the affected muscle, pain during atmospheric changes, and during or following exercise. The stiffness with contraction sometimes results in restriction of motion of the joint.

Conclusions

- 1 Proper treatment of muscle injuries requires a thorough knowledge of pathological processes.
- 2 Treatment of minor injuries reduces discomfort and the period of disability.
- 3 Treatment of severe injuries often prevents permanent pathological changes.

A SOUND POLICY

The Cleveland Academy of Medicine has recently informed the city Board of Education that injured athletes should be

cared for by physicians chosen by the family and not by the board of education.

REVIEW OF RADIOGRAPHS OF INFECTIOUS ARTHRITIS

Twenty-Four Cases—One to Four Years Following Fever Therapy

SOL C. DAVIDSON, M D, and STAFFORD L. WARREN, M D, *Rochester*

We are concerned in this study with the changes which might be shown in radiographs of joint structures in patients who have received either fever therapy alone, or a combination of fever therapy and a hot bath routine as the sole treatment for relief of symptoms associated with infectious arthritis.

Out of a series of eighty cases treated or observed over a period of from one to three years, there are only fifty-one who have had preliminary films or radiographic examinations for diagnostic purposes. But there were only twenty-four of this group in which it was possible to obtain films both before and after the treatment period. A part of this case mortality is perhaps due to the failure in the effectiveness of the treatment, but, in general, the failure to obtain films before and after a suitable period following treatment was due to economic factors. Neither the patient nor the clinic had funds to pay for this examination. We have restricted our study therefore, to those patients from whom we have sufficient follow-up radiographic examinations to warrant some conclusions, with the distinct understanding that this does not represent a true cross-section of the whole group which has been under observation. Of this group of twenty-four, there have been three cases which have definitely not been influenced by the treatment from either the clinical or the radiographic standpoint. There have been six cases which have had definite clinical improvement, but there is no radiographic evidence of definite change in the bony structures around the joint to support this improvement. This makes a total of nine cases, or approxi-

mately thirty-eight per cent failures, or sixty-two per cent showing definite radiographic and clinical evidence of improvement, in these twenty-four cases.

It might be argued that these cases would have improved this much any way over a period of from one to three years, but this argument may be dismissed by the fact that these cases had all been under various other kinds of treatment suggested by the various clinicians for periods varying from one to seven years, with continued progression of the disease. A good many cases had either been partially or totally incapacitated at the onset of treatment, with a history of repeated subacute exacerbation of symptoms frequently accompanied by spontaneous fever and swelling and pain in the joints. All of the patients were studied thoroughly in the hospital before fever treatment. All of them have had various foci of infection removed. No attempt was made to regulate the diet, the patient having been told to keep on a good general diet with, perhaps, the only change being the addition of one quart of milk a day. In a few of the earlier cases, cod liver oil and liver were prescribed to take care of the anemia, but this was found to be unnecessary, and was discontinued in the later cases since the anemia seemed to improve spontaneously a short time after the joint symptoms became quiescent. Each patient gained from ten to twenty pounds in weight and improved in his general physical condition.

The method of treatment, after the patient had had a complete physical examination, electrocardiogram, and chest film, was to give a short artificial fever at 40.5°C maintained for a period of four hours. The patient was placed in a cabinet with the radiation from five

Aided by a grant from the Rockefeller Foundation for Medical Research

try which might precipitate what he called a dramatic recovery. The fever therapy was outlined to him and we administered it over a period of twenty-one days for the reason that he seemed to be unusually suggestible to chemical measures. After discontinuing the fever series he insisted that he was greatly improved, but after several weeks he returned to his former complaints of mental and physical fatigability, irritability, sullenness and depression. His real problem was one of guilt in connection with his marital affairs, but he proved to be too surly and stubborn to be cooperative in the smallest degree with his physician. He therefore drifted along.

A woman, aged forty, was given this fever treatment for the uncommon condition of abdominal migraine. This condition was a conversion expression of hysteria in her case. Although her state was discovered to be a question of personality background and the involvement in a love disappointment, she insisted on being treated on what she called a strictly medical basis—meaning, of course, medication and physical manipulation. She cleverly perceived at once that the object of the injection was to divert her attention from her abdominal organs, and insisted that we were on the wrong track. The sulphur was discontinued as useless. She ultimately recovered through a practical, sensible psychological management of her personality and emotional drives.

A young woman in an acute state of hysterical resistiveness and anger was given this treatment, but after two injections it was likewise discontinued for the reason that there was no favorable response. Her problem was also a love affair.

Another woman, aged forty-seven, had a character neurosis of many years' standing. Superimposed on this was a motivated depression, due to a hurt pride over her mismanagement of an estate. Because all psychiatric efforts had failed, she was given this treatment experimentally. She had feelings of depersonalization and no zest for life. Prior to her coming to Stony Lodge she had made suicidal attempts. After several injections the fever regime was discontinued because it became apparent that it could not possibly influence the deeper layers of her mind and therefore contribute anything representing constructive treatment. As soon as she suspected that an invasion was being attempted on her obsessive state, she sarcastically remarked that the doctors were too meddlesome, that she proposed to live out her life in her own way, and she continued to be on the constant lookout for an opportunity to destroy herself.

Manic-depressive Psychoses

Sulphur therapy was employed in case of two young women undergoing acute manic attacks. It was sought to reduce mental flight and motor excitement. But the fevers did not in any way seem to change the clinical picture, so that it was necessary to return to prolonged baths and other expedients. Likewise, two women with depressions of many months duration did not respond to this treatment. It was sought to lighten the load of their depression. No success was obtained from this procedure. One of these depressed patients inquired if persons felt better with fever, and the other argued that she would prefer prolonged sleep by drugs.

Alcoholism

Three men and two women under treatment for acute alcoholism were given sulphur injections, *first*, for the purpose of increasing their general metabolism, *second* to bring them into a manageable mood. They were psychopathic personalities with definite, outstanding problems involving morals. Although they submitted readily to treatment, it was difficult to conclude how much direct benefit they derived from it. They were under the impression that the fever and sweating process eliminated the alcohol quickly and thoroughly from their organs and tissues. There was no evidence of any permanent psychic effect and real benefit since every one insisted, in the usual egotistical manner, upon the shortest period of treatment possible, and as a matter of fact, subsequent reports showed that they had returned to their former drinking habits.

Conclusions

In the treatment of five alcoholic, three psychoneurotic, four manic-depressive, and eight schizophrenic patients with intramuscular injections of sulphur-in-oil, it was found that the induced fever proved a useful means of frequently thwarting episodes of catatonia in schizophrenic patients. No change was observed in the flight of ideas and motor excitement of manics, or in deep depressive attitudes, or in somatic conversion symptoms of hysterical subjects.

Experience with fever therapy at Stony Lodge coincides generally with that reported by W. Gerson in schizophrenia (*Arch. f. Psychiat.* 98 614, 1933).

of the bone and subsidence of symptoms. The third case has shown an increase in calcium content, but has had several mild exacerbations of symptoms, and has been considered a failure.

The fifth group in the subacute and chronic types has been characterized by destruction of the cartilage as the main abnormality, and early ankylosis as the characteristic complication. There is very little proliferation of the soft tissues around the joint. Most of the skeleton was involved to some extent. In neither of the two cases treated has there been any definite improvement, except for a gain in weight, nor was the process halted by the treatment.

In the sixth group there are two cases in which a mixture of subacute and chronic soft tissue proliferation and bone atrophy, with the bone spur formation characteristic of degenerative arthritis, has occurred. In one of these, the changes characteristic of soft tissue proliferative arthritis have improved radiographically in that there is an increase in the density of the bone trabeculae and a subsidence of the atrophy. The other case has improved in physical condition, but still has exacerbation of the symptoms even one year after the combination treatment. There was no change in the radiographic appearance of the spurs of the degenerative phenomena.

It is of interest to point out that two cases are not considered in this series because they are classified under the

group of degenerative (hypertrophic) arthritis, the main characteristic being the formation of bony spurs. Complete relief from symptoms was obtained, although there has been no change in the radiographic appearance of the joints.

Conclusion

In conclusion, the cases in the acute stage of the soft tissue proliferative type of infectious arthritis have not been benefited by the treatment to the point where they show clear-cut changes radiographically. The group in which the cartilage is affected and ankylosis has developed has likewise not been affected. These are all young individuals below the thirty year age level. The others show a very marked improvement and are in the thirty to fifty year age group.

The percentage of cases showing definite improvement by radiographic observation is sixty-two per cent of the twenty-four cases of infectious arthritis in which follow-up films are available. If it had been possible to obtain films in all cases treated, our figures might be far different than this percentage would indicate. However, this conclusion seems consistent with the clinical improvement noted in the other patients as well.

CHEMISTS DEMAND NEW FOOD AND DRUG LAW

Restating its profound conviction that the present federal food and drugs act is too limited in its scope to afford the public necessary protection in the matter of foods, drugs and cosmetics, the American Pharmaceutical Association at its eighty-fourth annual convention, held at Dallas, Texas, urged the prompt enactment of legislation substantially the same as S 5 as it was passed by the Senate in 1934. The association further registered strong opposition to any provision in the proposed legislation which would lessen enforcement efficiency and stated that additional delay in enacting food and drug legislation should

be looked upon as a flagrant disregard of the public welfare.

State legislation to compel manufacturers to place definite information on the labels of their drug products showing the name and address of the source of production and state laws to restrict the distribution of drugs, medicines and medical supplies to registered pharmacists were also urged. The association plans to collect and coordinate factual information which will show the relationship between the quality and reliability of drugs and medicines and their sources of production and channels of distribution.

200 watt lamps directed at the trunk and limbs, the head remaining outside. This equipment has been described elsewhere in detail¹. At the end of treatment, there is usually complete relief of all joint symptoms, which lasts in all cases from twenty-four hours to a week. Following this, some of the symptoms may return, but, over the next five or six weeks, there is a steady gradual improvement in most of the cases. Those in whom this relief does not occur will be discussed later.

At various periods of months or a year or more after this treatment, exacerbations of mild character developed which were not severe enough to warrant giving the patient a second fever therapy. As a result, a hot bath routine was instituted, and, in the last two years, this has been advised for all patients who had had the fever treatment, and has been continued throughout the cold months of the year.

A consideration of the various types of this disease (infectious arthritis) and the regions involved is of some importance. Most of the patients studied had one or more joints of the extremities affected severely by the arthritic process. It is possible to divide up the groups into six major classifications, each quite distinct from the other. There are three patients with soft tissue proliferation involving the structures around the joint in the hands, wrists, feet, and ankles. All three patients are young women who have had the disease approximately one year before coming for treatment. There is very little atrophy or deformity, and no bone destruction. In one of these cases, there was absolutely no benefit derived from the treatment. In the other two, the immediate acute symptoms were arrested. These two patients have had a series of subacute exacerbations of swelling and pain since treatment, although they are in better physical condition and the exacerbations do not last very long. Radiographic examination of their joints does not show any definite diminution of the soft tissue proliferation and they are listed among the failures.

The second group is in the subacute or chronic stage, with frequent exacerbations of spontaneous fever, local symp-

toms of swelling, heat, and pain involving the joints of the extremities. The group may be roughly divided into two parts, the first one in which atrophy of joint structures and soft tissues is the predominant factor. The articulating surfaces are in part destroyed, with great thinning of the cartilage and bone atrophy. Of the ten in this group, nine showed very definite increase in the number and density of the trabeculations of the bony structures, and an increase in the sharpness of the bony structures beneath the cartilage, after treatment. In some instances, there has been further diminution of the thickness of the cartilage and an increase in deformity, although clinical and functional improvement was marked. The general atrophy is diminished. The cases in the second part are very much like those just described except that there is a great deal more actual destruction of the cartilage and joint surfaces, and some ragged bone proliferation at the joint margins not characteristic of the degenerative type. Two of these, after treatment, have shown recalcification of the bony surfaces beneath the cartilage, and the general increase in density and number of trabeculae of the bony structure around the joint. There has been no increase in deformity. The third case has shown some improvement in calcium content of the bony structure, but has been classified among the failures because of subsequent flare-up and the disappearance of the patient from follow-up during the last year.

Another division in this group may be considered in which the pathology in the joint has been aggravated by the development of a large pannus as shown in one case which shows the same radiographic evidence of improvement.

A fourth group of the subacute and chronic type consists of three patients wherein the spine has been practically the only part of the bony skeleton involved by the arthritic process. This has been characterized rather graphically by the generalized diminution in the calcium content of the vertebral bodies including the articulating facets, and a diminution in the number of trabeculae visible on the film. Two of these cases have shown increase in calcium content

plasia of the columnar epithelium of Lieberkühn's glands which are finally broken through to develop adenocarcinoma usually graded one plus or two

Rectal bleeding is noted in two-thirds of the cases, constipation in one-half of them, and occasionally extrusion at stool of a large tumor and those with a long pedicle. Too much emphasis cannot be placed upon the clinical experience that many a small but potentially dangerous tumor is symptomless.

Diagnosis is made by digital palpation and sigmoidoscopy, to be followed by a roentgen study of the colon to detect other or associated lesions at a higher level.

Treatment

A sessile tumor is destroyed by fulguration through a bakelite operating proctoscope. An accessible pedunculated growth may be ligated near the mucosa and ablated, if situated at a higher level, the pedicle is severed with the high-frequency electric snare passed through the tube.

Every tumor so removed should be submitted to a competent pathologist. If malignant changes are found, the site of removal should be implanted with gold seeds of radon. A follow-up examination should be made at intervals of six months for three years. In the few instances where two or more neoplasms are present in the same patient, each tumor is treated as outlined.

Multiple Neoplasms

Multiple polyposis and adenomatosis coli present a serious clinical problem. A simple but practical classification is (1) Adenomatosis coli, the congenital (adolescent) disseminated type, and (2) Pseudoadenomatosis, the acquired (adult) inflammatory multiple polyposis.

The so-called congenital or familial type is a grave but fortunately rare condition, only about 129 cases having been reported. The distal colon and the rectum are the commonest sites of these disseminated tumors, but higher segments or the entire large bowel may be involved.

Thorebeke,⁷ in a review of thirty-four cases, found the rectum involved in twenty-three, colon and rectum in five, the colon alone in six.

In Doering's compilation⁸ of fifty cases, children were affected more frequently than adults, and the ratio of males to females was about 2:1. The two earliest instances in my experience were boys, age five and seven years respectively.

The etiology is obscure. A traceable familial tendency has been noted in several cases. The theoretical basis of origin is a congenital tissue defect or a preternatural sensitivity of the mucosa whereby response to ordinary bacterial, chemical or traumatic stimuli is expressed in hypertrophy and hyperplasia.

The tumors at first are small and mostly sessile, but tend to become pedunculated as a result of growth and the traction of hyperperistalsis. Individual tumors vary from a millimeter to two centimeters in diameter. Trauma of the feces and infection may cause peripheral ulceration.

The process is slow but progressive over a period of two to five or more years. Hemorrhagic diarrhea may quickly deplete the patient, but the chief danger of neglect or inadequate treatment is the tendency of the adenomata to undergo malignant degeneration. Statistics of Doering, Soper, Tuttle, and others show an adenocarcinomatous change in from forty-three to fifty per cent of cases. Accumulating clinical experience indicates that, in their natural course, all cases of disseminated adenomatosis coli eventually undergo malignant degeneration, frequently multicentric.

By histologic study of removed specimens, the transition has been traced through the stages of gland-cell hyperplasia and hypertrophy of the adenoma to definite adenocarcinoma. The nature of the carcinogenic impulse is not definitely known, but its continued action finally results in the hypertrophied anaplastic gland epithelium, with deeply staining nuclei and diminished production of mucus, breaking through normal bounds and becoming a true adenocarcinoma, occasionally of grade three or four.

Fitzgibbon and Rankin,⁹ in a critical study of thirteen cases of localized or generalized polyposis of the colon and rectum, found twenty-four carcinomata in eleven or eighty-five per cent of these cases. These investigators presented convincing histologic proof that twenty-two (92%) of the twenty-four carcinomata were de-

ADENOMATA

Relation to Rectocolonic Carcinoma

FRANK C YEOMANS, MD, FACS, New York City

Professor Proctology New York Polyclinic Medical School and Hospital

Polyp refers to the form and not to the histologic structure of a neoplasm. This paper is limited to adenomas of the intestinal mucosa, excluding other rare benign polypoid tumors, such as lipomas, fibromas, myomas, and angiomas, which combined comprise only about one-tenth of all benign intestinal growths. Approximately seventy-five per cent of intestinal adenomata occur in the colon and rectum.

Lawrence,¹ in a series of 7,000 autopsies at the Cook County Hospital (1929-1935), found 166 cases of adenomatous polyps of the colon, in 102 of which the tumors were localized to a segment and in thirteen distributed throughout the colon and rectum. Six colonic polyps had undergone malignant change, an incidence of 3.6 per cent, and carcinomas were associated in nineteen cases (11.44%), making a total malignancy incidence of 15.6 per cent.

Rectal polyps were present in thirty cases, sixteen of these cases having polyps elsewhere, chiefly in the colon. Of the thirty rectal polyps, five (16.6%) were malignant, cancers were associated in three cases, making a total rectal malignancy of 26.6 per cent.

White males were most frequently affected and the average age was thirty-two to fifty-six years. Diverticula were present in twenty-two (13.2%) of the 166 cases and ulcerative colitis in only three instances.

Lawrence's findings show significantly that the number of polyps more closely approaches the number of malignancies in the sigmoid and rectum than elsewhere in the gastrointestinal tract.

Dukes found polyps associated with twenty-five (75%) of thirty-three consecutive cases of carcinoma of the sigmoid and rectum removed at operation.

Lockhart-Mummery² considers the tendency so marked for simple adenomata to become malignant that he "looks upon adenomata as merely a stage in the development of malignant disease."

Buie and Brust³ observed 143 cases of solitary adenoma of the pelvic colon and rectum in eighty-four males and fifty-nine females. Four-fifths of the patients were between thirty-five and sixty-five years of age. The situation of the tumor was rectum, 52.5 per cent, colon, 47.5 per cent.

A polyp was felt in only forty-two of these cases, sigmoidoscopy revealing the others. Roentgenograms showed other lesions in only two cases, both diverticula. In a five-year follow-up of fifty of fifty-six cases treated by fulguration or by surgical excision, there were no recurrences. Of the eighty-seven cases not treated, twenty-four were not traced, fifty-five were alive and well, four died of other diseases, and four developed carcinoma of the lower sigmoid or rectum.

The laboratory records of the N Y Polyclinic Hospital for the seven years (1929-1935) show seventy-one adenomatous polyps, twenty-one (42%) of which were malignant. During the same period there were 171 cases of carcinoma of the rectum and sigmoid, eight (4.7%) of which had associated adenomata.

Some thirty-five cases of polypoid tumors of the pelvic colon and rectum in children have occurred in my practice, none of which was malignant.

In a previous communication⁴ I reported seven cases of rectal adenomata in adults which had undergone malignant degeneration. Six additional cases now bring the number to thirteen.

The precise etiology of an adenoma is unknown. Histologic studies carry them through the stages of hypertrophy of the mucosa and pedicle formation, and hyper-

plasia of the columnar epithelium of Lieberkuhn's glands which are finally broken through to develop adenocarcinoma usually graded one plus or two

Rectal bleeding is noted in two-thirds of the cases, constipation in one-half of them, and occasionally extrusion at stool of a large tumor and those with a long pedicle. Too much emphasis cannot be placed upon the clinical experience that many a small but potentially dangerous tumor is symptomless.

Diagnosis is made by digital palpation and sigmoidoscopy, to be followed by a roentgen study of the colon to detect other or associated lesions at a higher level.

Treatment

A sessile tumor is destroyed by fulguration through a bakelite operating proctoscope. An accessible pedunculated growth may be ligated near the mucosa and ablated, if situated at a higher level, the pedicle is severed with the high-frequency electric snare passed through the tube.

Every tumor so removed should be submitted to a competent pathologist. If malignant changes are found, the site of removal should be implanted with gold seeds of radon. A follow-up examination should be made at intervals of six months for three years. In the few instances where two or more neoplasms are present in the same patient, each tumor is treated as outlined.

Multiple Neoplasms

Multiple polyposis and adenomatosis coli present a serious clinical problem. A simple but practical classification is (1) Adenomatosis coli, the congenital (adolescent) disseminated type, and (2) Pseudoadenomatosis, the acquired (adult) inflammatory multiple polyposis.

The so-called congenital or familial type is a grave but fortunately rare condition, only about 129 cases having been reported. The distal colon and the rectum are the commonest sites of these disseminated tumors, but higher segments or the entire large bowel may be involved.

Thorebeke,⁵ in a review of thirty-four cases, found the rectum involved in twenty-three, colon and rectum in five, the colon alone in six.

In Doering's compilation⁶ of fifty cases, children were affected more frequently than adults, and the ratio of males to females was about 2:1. The two earliest instances in my experience were boys, age five and seven years respectively.

The etiology is obscure. A traceable familial tendency has been noted in several cases. The theoretical basis of origin is a congenital tissue defect or a preternatural sensitivity of the mucosa whereby response to ordinary bacterial, chemical or traumatic stimuli is expressed in hypertrophy and hyperplasia.

The tumors at first are small and mostly sessile, but tend to become pedunculated as a result of growth and the traction of hyperperistalsis. Individual tumors vary from a millimeter to two centimeters in diameter. Trauma of the feces and infection may cause peripheral ulceration.

The process is slow but progressive over a period of two to five or more years. Hemorrhagic diarrhea may quickly deplete the patient, but the chief danger of neglect or inadequate treatment is the tendency of the adenomata to undergo malignant degeneration. Statistics of Doering, Soper, Tuttle, and others show an adenocarcinomatous change in from forty-three to fifty per cent of cases. Accumulating clinical experience indicates that, in their natural course, all cases of disseminated adenomatosis coli eventually undergo malignant degeneration, frequently multicentric.

By histologic study of removed specimens, the transition has been traced through the stages of gland-cell hyperplasia and hypertrophy of the adenoma to definite adenocarcinoma. The nature of the carcinogenic impulse is not definitely known, but its continued action finally results in the hypertrophied anaplastic gland epithelium, with deeply staining nuclei and diminished production of mucus, breaking through normal bounds and becoming a true adenocarcinoma, occasionally of grade three or four.

Fitzgibbon and Rankin,⁷ in a critical study of thirteen cases of localized or generalized polyposis of the colon and rectum, found twenty-four carcinomata in eleven or eighty-five per cent of these cases. These investigators presented convincing histologic proof that twenty-two (92%) of the twenty-four carcinomata were de-

Fig 1 Solitary polypoid adenoma of rectum—proctoscopic. Removable by electric snare passed through proctoscope.

rived from polyps. They feel that the evidence presented "argues persuasively for the extremely plausible contention that the histogenesis of carcinoma of the colon is mediated through precancerous polyp formation and not otherwise."

As malignant transition may occur in widely separated tumors, negative findings in two or more excised growths do not exclude the possibility of other neoplasms in the same patient being malignant.

Pseudopolyposis

Acquired or inflammatory type

Rokitansky, in 1839, and Woodward, in 1881, interpreted the polyps developing in the margin of ulcers as islets of mucosa isolated by the cicatricial tissue in the process of repair.

Disseminated tumefactions have thus been frequently observed, especially in the ulcers of dysentery and of chronic ulcerative colitis. The undermined mucosa at the margin of the ulcer appears as a polypoid tumefaction which contains inflammatory and granulation tissue. Nests of glands are caught in the inflammatory fibrous network and closure of the glandular orifices by the inflammatory process frequently results in retention cysts. The histologic feature that distinguishes these tumors, of apparently infectious origin, from ordinary adenomata is the marked increase of inflammatory and fibrous tis-

sue, with simple inflammatory ulceration at or near the base and scarring between the polyps.

The most serious complications of chronic ulcerative colitis may be acute or chronic. The acute are massive hemorrhage from an eroded blood vessel in the base of an ulcer, and perforation of an ulcer, resulting in an abscess or peritonitis. The slower chronic results are fibrosis of the bowel wall with stricture formation, and multiple polyposis. Polyposis is the commonest complication and the rectum is its usual site of origin.

Bargen and Comfort⁸ reported sixty-nine instances of polyposis, as a complication, in 693 cases of chronic ulcerative colitis. The ratio of multiple inflammatory polyp cases to adenomatosis coli was four to one. Malignant disease was proved in twenty-three of these cases: twenty were carcinoma, two lymphosarcoma, and one lymphatic leukemia. Eighteen of the patients were between twenty-one and forty-five years of age.

Symptoms suggestive of a malignant change are abrupt increase of colicky pain and bloody dejecta, rapid weight loss, and varying degrees of obstruction. An abdominal mass may be palpable. Proctoscopy frequently reveals the malignant lesion associated with polyps, and roentgenograms show filling defects in addition to the usual picture of chronic ulcerative colitis.

Personally I have observed five patients

Fig 2 Multiple sessile adenomata of rectum, sequel to chronic ulcerative colitis, destroyed by fulguration.

with polyposis of the colon, one of whom developed cancer

J T, male, age twenty-nine, had a history of dysentery of fourteen months' duration. Stools averaged fifteen daily and contained pus and blood. The patient was anemic, felt weak, and had lost twenty pounds in weight. Sigmoidoscopy disclosed multiple adenomata, varying in size from a pea to a hazelnut, and others beyond the reach of the tube. I established a colostomy in the transverse colon, as no tumors were palpable through the bowel wall above the sigmoid. Unfortunately, when the gut was opened on the fifth day it was found that the adenomata extended to the hepatic flexure and presumably to the cecum.

As a result of diversion of the fecal current and irrigations, many of the tumors distal to the stoma disappeared or regressed. The growths proximal to the stoma were influenced to a lesser degree, yet the patient regained his weight and strength and pursued his usual occupation for three years. Then intractable diarrhea occurred through the colostomy and in response to the patient's urgent request for radical relief, an ileostomy was established. Uncontrollable discharge

Fig 4 Low power enlargement of a polypoid growth from colon in Fig 3

through the ileostomy quickly sapped his vitality and he succumbed three weeks later.

The excised colon distal to the colostomy was contracted, its walls were thickened and leathery, and many small adenomata studded its mucosa. The proximal colon showed adenocarcinomatous degeneration of large areas, but many unchanged adenomata were still present.

Treatment

Irradiation is not effective. No case has been reported as cured by the x-ray or radium.

All accessible adenomata in the rectum and pelvic colon should be destroyed by fulguration or removed with the electric snare passed through the operating proctoscope.

Temporary colostomy was successful in a man, age forty-one, upon whom I operated in February 1930, for bleeding from adenomata localized to the pelvic colon and rectum. If a colostomy can be made in sound gut well above the adenomata, I feel that it is a worth-while and useful procedure. By it the adenomata are freed from the irritation of the intestinal contents, the benefits of local treatment are made available, fulguration and elec-

Fig 3 Section of colon showing multiple polyposis secondary to chronic ulcerative colitis, non-specific. (Male, age fifty-four)

tric snaring are facilitated and, if treatment proves successful, the stoma may be closed, as was done in the case above cited.

For tumors disseminated throughout the colon, nothing short of total colectomy is effective. If the rectum and lower pelvic colon are or can be cleared of the tumors, the indication is ileosigmoidostomy, to be followed by colectomy. Otherwise, a transverse ileostomy is established and later colectomy is performed in stages.

Summary and Conclusions

Sigmoidoscopy should be done in every patient having symptoms referable to the colon or rectum, as hemorrhoids, rectal bleeding, pain or discomfort, or sciatica, persistent diarrhea, progressive constipation, or a feeling of incomplete relief after evacuation.

Any growth, however small and innocent in appearance, should be destroyed by fulguration, or, if excised, submitted to a competent tumor pathologist. In my series of solitary adenomata, thirteen proved to be malignant.

Prompt removal of an adenoma is the only guarantee against its later change into adenocarcinoma.

A follow-up examination at intervals of

six months for three years should be made.

Multiple polyposis and adenomatosis coli are grave conditions requiring major surgery for relief.

Convincing proof is presented of malignant degeneration, frequently multicentric, in both groups of disseminated growths.

Significant facts are that adenomata develop particularly in the cancer age and that their number more closely approaches the number of cancers in the sigmoid and rectum than elsewhere in the gastrointestinal tract.

Doubtless carcinoma of the colon and rectum is frequently mediated through an adenoma but, as yet, we cannot affirm that all rectocolonic cancers originate from adenomata.

NEXT PUBLIC HEALTH CONVENTION TO MEET IN NEW YORK CITY

The American Public Health Association announces that its 66th Annual Meeting will be held in New York City, October 5-8.

A large Eastern membership will receive that information with satisfaction. Not since 1921 has the Association met in the world's greatest city.

The sixty-fifth Annual Meeting in New Orleans last October, attracted an attendance of 1650 health authorities representing forty-five states, Canada, Cuba, Mexico, and nine other foreign countries. The officers of the Association are reminding themselves of this registration in a state where the membership numbers less than 100 and asking themselves what the registration will be in New York City where the membership counts up to nearly 500 within the city limits alone. An overnight's

ride will enable more than one-half of the Association's 5,000 members to attend.

The National Organization for Public Health Nursing will meet with the American Public Health Association in 1937 for the first time. This large and important organization is expected to add another thousand to the registration lists.

The following related societies will meet with the Association as usual: The American Association of School Physicians, International Society of Medical Health Officers, Conference of State Sanitary Engineers, Conference of State Laboratory Directors, Association of Women in Public Health, Delta Omega.

Dr Reginald M. Atwater is the Executive Secretary of the Association, and the headquarters offices are at 50 West 50 Street, New York City.

TRAUMATIC SUBCUTANEOUS EMPHYSEMA OF THORACIC ORIGIN

JOSEPH B STENBUCK, M D, *New York City*

The term *mediastinal emphysema* is loosely applied to the condition in which air arises within the thorax and presents itself beneath the skin as a more or less diffuse crepitant swelling. It is frequently used synonymously for subcutaneous emphysema. *Mediastinal* is a misnomer in the vast majority of traumatic cases, since of the several sources of air, the mediastinum is one of the least frequent. In our experience mediastinal emphysema is, with few exceptions, secondary to a subcutaneous emphysema which is first produced superficially in the thoracic wall. This subcutaneous emphysema rising to the neck may then descend into the mediastinum if the pressure is sufficient. We have seen it occur, too, in cases of lacerated trachea in the neck in which the skin wounds were tightly packed and air was forced from the trachea downwards into the mediastinum. We have no experience with mediastinal emphysema which is said to occur when a bleb situated on the hilar surface of the lung bursts and allows air to issue directly into the mediastinum.

In the majority of traumatic cases subcutaneous or interstitial emphysema is a more appropriate name than mediastinal emphysema and the name may be modified according to the source of air.

1 *Needle puncture* Exploration of the chest with the aid of the aspirating syringe and the introduction of a needle to produce artificial pneumothorax are common medical procedures. It is not uncommon to find a small area of subcutaneous emphysema at the site of puncture. This may have arisen from the air introduced directly into the subcutaneous tissues from the syringe. If a pneumothorax were present, and the hole in the parietal pleura did not close immediately on withdrawal of the needle, air might be forced from the pleural cavity into the subcutaneous tissues during respiration and continue

until all the air constituting the pneumothorax were expelled. If, in addition, the lung were punctured by the needle and a continuous stream of air escaped from the alveoli into the pleural cavity, an unlimited amount of air might thus be forced into the subcutaneous tissues. This condition is extremely rare.

Subcutaneous emphysema may arise after needle puncture when gas producing organisms, withdrawn from areas of pleural or pulmonary suppuration, are deposited in the chest wall and produce gas. Crepitation may be felt, but there is usually also present an abscess or a phlegmon. The problem in these cases is not one of subcutaneous emphysema but of infection of the chest wall.

Not infrequently crepitation may be felt after a hyperdermoclysis of normal saline solution. It is possible that the pleura may have been punctured, but not likely. Air is usually introduced from the tubing, or, rarely, by infection with a gas producing organism in cases where sterility is not maintained.

2 *After thoracotomy for emphysema* we have occasionally seen subcutaneous emphysema extend in varying amounts from the region of the wound. This has occurred even when the wound has been kept open widely. However, it has never been of any clinical importance.

3 *Penetrating wounds of the chest* are frequently accompanied by subcutaneous emphysema. In a series of sixty-eight consecutive cases of penetrating wounds of the chest in a period of eleven months in which thoracotomy was performed, we found subcutaneous emphysema in forty per cent of the cases.¹ Only one case of stab wound of the chest showed subcutaneous emphysema without penetration. This was apparently due to the vigorous action of the chest muscles sucking air into tissue planes. Subcutaneous emphysema may be considered a cardinal

sign of penetration, therefore This penetration, however, need not extend beyond the parietal pleura, i.e lung parenchyma may be intact This type of subcutaneous emphysema has been extensive enough to require treatment at Harlem Hospital but once in the past six years It is represented in the following case

CASE 1 A B, age thirty-nine, was admitted to Harlem Hospital, July 1, 1930 He was seen about a half hour after having been

curred a prompt and rapid spread of subcutaneous emphysema starting from the region of the wound It spread to the head, neck, and arms, and downward over the trunk and upper portion of the thighs Within six hours the patient's eyes were tightly closed by crepitant swelling and he complained of such difficulty in swallowing even water, and of such a terrifying sense of suffocation, that operation for relief was imperative Under novocain anesthesia, July 3, a five inch horizontal incision was made over the third intercostal space. The exploratory incision was made below the

Fig 1 (A) The lung moves away from the chest wall causing air to be aspirated from outside the chest wall into the pleural cavity The air follows the tract caused by the instrument of penetration. *a*, represents the skin, *b*, the subcutaneous tissues, *c*, the parietal pleura, and *d*, the visceral pleura.

(B) The lung moves toward the chest wall increasing the pressure in the pleural cavity, thus forcing the air out of the pleural cavity A valve-like action of some of the subcutaneous tissues—particularly of fascia and muscle—prevents this air from reaching the atmospheric air It is therefore forced into the various subcutaneous planes This process may continue with each respiration until air is pumped throughout the body, giving rise to diffuse subcutaneous emphysema.

If, in addition to the laceration of the chest wall, the lung is lacerated there is an additional source of air which may be pumped into the subcutaneous tissues

stabbed by an assailant wielding a long butcher's knife There was a one and one-half inch wound of the right chest over the second intercostal space in the mid-clavicular line Subcutaneous emphysema was present over an area three inches in diameter The patient was quite dyspneic and complained of pain in his right chest An interesting phenomenon occurred at the site of the chest wound Here a globular, soft swelling in the subcutaneous tissues became larger with inspiration and smaller with expiration This was thought to be protruding lung caught in a lacerated intercostal space. This swelling remained *in situ* for about thirty hours when it disappeared When the swelling disappeared, there oc-

stab wound because the course of a stab wound in the chest is usually directed caudad. The intercostal muscles and the pleura were found severed for a distance of three and one-half inches (This disparity in the length of the skin wound and the pleural wound, may be explained by the fact that after being plunged into the chest, the knife was rocked back and forth with the tougher skin as a fulcrum) (Thus, great damage may be done beneath a small skin wound) There was considerable blood in the pleural cavity which obscured a view of the lung On coughing, however, the lung protruded for a distance of an inch and a half forming a globular mass which was probably the subcutaneous mass seen

SUBCUTANEOUS EMPHYSEMA

February 15, 1937]

on admission, rising and falling with respiration. The lung and pleural cavity were explored locally. The laceration of the intercostal muscles and parietal pleura was sutured and the pectoralis major muscle sutured over it forming an air tight closure. A superficial drain was inserted to allow for escape of serum from the subcutaneous tissues.

After operation, the subcutaneous emphysema which had been spreading rapidly, ceased to spread, and there was relief from dysphagia and dyspnea. The relief was so marked that the patient felt well enough to

CASE 2 J.L., age forty-two, was admitted to the Harlem Hospital, October 8, 1933, and discharged November 13 (Fig 3 and 4). He had been struck by an automobile and received the following injuries (a) fractured ribs, right, (b) fractured clavicle, right, (c) fractured tibia and fibula, right. Subcutaneous emphysema was present on admission, localized to the right axilla and pectoral regions, but spread until it involved the entire trunk, the head, both arms, and the upper portion of both thighs. The eyes were completely closed. The scrotum was ballooned to such proportions that the penis

Fig 2 Subcutaneous emphysema which arises in cases without penetration of the skin. As a rule in traumatic cases this is due to a fractured rib which has penetrated the visceral and parietal pleuras, the lung, and subcutaneous tissues.

(A) The lung moves away from the chest wall. Air escapes from the alveoli of the lacerated lung into the pleural cavity. Note how the fragment of fractured rib has acted like a dagger, producing a "subcutaneous stab wound of the chest."

(B) The lung moves toward the chest wall thus increasing the pressure in the pleural cavity, and forcing the pleural air through the lacerated parietal pleura into the subcutaneous planes. As in Fig 1 this may continue until subcutaneous emphysema extends over the entire body.

leave the hospital July 7, although he was advised to stay for further observation. At present, six years after operation he is alive and well.

4 *Fractured ribs* are not infrequently accompanied by subcutaneous emphysema. It is advisable to consider fractured ribs not as broken bones but as dagger-like objects producing concealed or *subcutaneous stab wounds of the chest*. In this way attention will be focused on the important complications, such as hemothorax, pneumothorax, and subcutaneous emphysema. Fortunately, subcutaneous emphysema does not assume formidable proportions. In the past six years at Harlem Hospital there was a single exception

was lost to view in it. There was no difficulty in breathing or swallowing at the onset, but gradually dysphagia and dyspnea appeared and about thirty-six hours after admission became acute and required immediate treatment. It was our opinion that the air producing subcutaneous infiltration originated in the pleural cavity from lung lacerated by broken ribs and that if it were possible to divert the air outside the body, further infiltration of the tissues would be avoided. Accordingly through an intercostal stab wound, a rubber tube was placed into the pleural cavity. The other end of the tube was submerged and fixed just below water level in a bottle. Air escaped and bubbled through the water on each expiration and particularly on coughing. In this way, air which had been rhythmically pumped into the subcutaneous tissues was

sign of penetration, therefore. This penetration, however, need not extend beyond the parietal pleura, i. e. lung parenchyma may be intact. This type of subcutaneous emphysema has been extensive enough to require treatment at Harlem Hospital but once in the past six years. It is represented in the following case.

CASE 1 A B, age thirty-nine, was admitted to Harlem Hospital, July 1, 1930. He was seen about a half hour after having been

curled a prompt and rapid spread of subcutaneous emphysema starting from the region of the wound. It spread to the head, neck, and arms, and downward over the trunk and upper portion of the thighs. Within six hours the patient's eyes were tightly closed by crepitant swelling and he complained of such difficulty in swallowing even water, and of such a terrifying sense of suffocation, that operation for relief was imperative. Under novocain anesthesia, July 3, a five inch horizontal incision was made over the third intercostal space. The exploratory incision was made below the

Fig 1 (A) The lung moves away from the chest wall causing air to be aspirated from outside the chest wall into the pleural cavity. The air follows the tract caused by the instrument of penetration. *a*, represents the skin, *b*, the subcutaneous tissues, *c*, the parietal pleura, and *d*, the visceral pleura.

(B) The lung moves toward the chest wall increasing the pressure in the pleural cavity, thus forcing the air out of the pleural cavity. A valve-like action of some of the subcutaneous tissues—particularly of fascia and muscle—prevents this air from reaching the atmospheric air. It is therefore forced into the various subcutaneous planes. This process may continue with each respiration until air is pumped throughout the body, giving rise to diffuse subcutaneous emphysema.

If, in addition to the laceration of the chest wall, the lung is lacerated there is an additional source of air which may be pumped into the subcutaneous tissues.

stabbed by an assailant wielding a long butcher's knife. There was a one and one-half inch wound of the right chest over the second intercostal space in the mid-clavicular line. Subcutaneous emphysema was present over an area three inches in diameter. The patient was quite dyspneic and complained of pain in his right chest. An interesting phenomenon occurred at the site of the chest wound. Here a globular, soft swelling in the subcutaneous tissues became larger with inspiration and smaller with expiration. This was thought to be protruding lung caught in a lacerated intercostal space. This swelling remained *in situ* for about thirty hours when it disappeared.

When the swelling disappeared, there oc-

curred a prompt and rapid spread of subcutaneous emphysema which obscured a view of the lung. On coughing, however, the lung protruded for a distance of an inch and a half forming a globular mass which was probably the subcutaneous mass seen

on admission, rising and falling with respiration. The lung and pleural cavity were explored locally. The laceration of the intercostal muscles and parietal pleura was sutured and the pectoralis major muscle sutured over it forming an air tight closure. A superficial drain was inserted to allow for escape of serum from the subcutaneous tissues.

After operation, the subcutaneous emphysema which had been spreading rapidly, ceased to spread, and there was relief from dysphagia and dyspnea. The relief was so marked that the patient felt well enough to

CASE 2 J L, age forty-two, was admitted to the Harlem Hospital, October 8, 1933, and discharged November 13 (Fig 3 and 4). He had been struck by an automobile and received the following injuries (a) fractured ribs, right, (b) fractured clavicle, right, (c) fractured tibia and fibula, right. Subcutaneous emphysema was present on admission, localized to the right axilla and pectoral regions, but spread until it involved the entire trunk, the head, both arms, and the upper portion of both thighs. The eyes were completely closed. The scrotum was ballooned to such proportions that the penis

Fig 2 Subcutaneous emphysema which arises in cases without penetration of the skin. As a rule in traumatic cases this is due to a fractured rib which has penetrated the visceral and parietal pleuras, the lung, and subcutaneous tissues.

(A) The lung moves away from the chest wall. Air escapes from the alveoli of the lacerated lung into the pleural cavity. Note how the fragment of fractured rib has acted like a dagger, producing a "subcutaneous stab wound of the chest."

(B) The lung moves toward the chest wall thus increasing the pressure in the pleural cavity, and forcing the pleural air through the lacerated parietal pleura into the subcutaneous planes. As in Fig 1 this may continue until subcutaneous emphysema extends over the entire body.

leave the hospital July 7, although he was advised to stay for further observation. At present, six years after operation he is alive and well.

4 *Fractured ribs* are not infrequently accompanied by subcutaneous emphysema. It is advisable to consider fractured ribs not as broken bones but as dagger-like objects producing concealed or *subcutaneous stab wounds of the chest*. In this way attention will be focused on the important complications, such as hemothorax, pneumothorax, and subcutaneous emphysema. Fortunately, subcutaneous emphysema does not assume formidable proportions. In the past six years at Harlem Hospital there was a single exception

was lost to view in it. There was no difficulty in breathing or swallowing at the onset, but gradually dysphagia and dyspnea appeared and about thirty-six hours after admission became acute and required immediate treatment. It was our opinion that the air producing subcutaneous infiltration originated in the pleural cavity from lung lacerated by broken ribs and that if it were possible to divert the air outside the body, further infiltration of the tissues would be avoided. Accordingly through an intercostal stab wound, a rubber tube was placed into the pleural cavity. The other end of the tube was submerged and fixed just below water level in a bottle. Air escaped and bubbled through the water on each expiration and particularly on coughing. In this way, air which had been rhythmically pumped into the subcutaneous tissues was

sign of penetration, therefore. This penetration, however, need not extend beyond the parietal pleura, i.e. lung parenchyma may be intact. This type of subcutaneous emphysema has been extensive enough to require treatment at Harlem Hospital but once in the past six years. It is represented in the following case.

CASE 1 A B, age thirty-nine, was admitted to Harlem Hospital, July 1, 1930. He was seen about a half hour after having been

injured by a stab wound. It caused a prompt and rapid spread of subcutaneous emphysema starting from the region of the wound. It spread to the head, neck, and arms, and downward over the trunk and upper portion of the thighs. Within six hours the patient's eyes were tightly closed by crepitant swelling and he complained of such difficulty in swallowing even water, and of such a terrifying sense of suffocation, that operation for relief was imperative. Under novocain anesthesia, July 3, a five inch horizontal incision was made over the third intercostal space. The exploratory incision was made below the

a period of six years, only two patients required active treatment. Their histories have been recorded above

The treatment most commonly described for extensive cases of subcutaneous emphysema in which there is difficulty in swallowing or interference with respiration has been that of multiple incisions. These incisions usually including one in the episternal notch, serve to allow air to escape from the subcutaneous tissues (particularly from the mediastinum) and to relieve the dyspnea and dysphagia. In the light of the mechanisms of subcutaneous emphysema it seems more logical to attack the problem at its source rather than to temporize with multiple incisions. The bicycle-pump action of the lung must be stopped. This may be accomplished in several principal ways. *First*, by induction of an artificial pneumothorax which compresses the lung and puts an end to its pumping. This method we mention purely as a theoretical consideration. We have not used it. *Second*, when the site of lacerated parietal pleura is known, by suturing or otherwise stoppering the hole in the parietal pleura. *Third*, by leading off the air directly from the pleural cavity, so that it may not be forced into the subcutaneous tissues. This was the method used in our second case described above. It is particularly applicable to cases of fractured rib where, with intact skin, the exact point of lacerated parietal pleura cannot be determined, or where there are multiple fractured ribs and corresponding multiple lacerations of the pleura. It may be accomplished by introducing a rubber tube at least one c.c. in diameter through an intercostal stab wound and leading the

other end of the tube under water. If a smaller tube, a needle or a cannula is used, the caliber may not be big enough to lead off the air which is being violently pumped out of the pleural cavity in large quantities.

If the site of injury cannot be determined in a case in which the patient is first seen with an extensive subcutaneous emphysema on both sides of the chest, a careful history must be obtained to determine upon which side the crepitation began. That is the side which should be attacked. It must be borne in mind that subcutaneous emphysema may begin on both sides simultaneously. In that case we should not hesitate to treat both sides. We have not had an opportunity to treat both pleural cavities simultaneously in a case of subcutaneous emphysema but have successfully done so in cases of bilateral tense pneumothorax in which the principal of air drainage is the same.

Summary

Diffuse subcutaneous emphysema arising in the chest in *traumatic cases* usually arises superficially in the chest wall and not in the mediastinum. The commonest causes in a traumatic service are penetrating wounds of the chest and fractured ribs causing laceration of the lung, without or with laceration of the chest wall. The simplest and most effective treatment consists in draining the pleural cavity of the air which might otherwise be pumped into the subcutaneous tissues, or repairing the laceration if the exact place is known.

WOMEN ORGANIZE FOR CANCER CAMPAIGN

Representatives from seven Eastern states have organized the Women's Field Army, which is being sponsored by the American Society for the Control of Cancer in a campaign of education addressed to the public. "Commanders" from Maine, New Hampshire, Delaware, New York, Pennsylvania, Rhode Island, and West Virginia heard addresses by Mrs. Grace Morrison

Poole, national adviser to the movement, and Clarence C. Little, Sc.D., director of the American Society for the Control of Cancer. The drive will be continued till March 27, the last week being devoted to enlistment of women as volunteers. After that time the army will go on a permanent basis and will conduct an educational campaign the year round.

Fig 3 Just after insertion of the tube for drainage of air from pleural cavity (Case 2) Subcutaneous emphysema was at its height and is extensive in head, trunk and scrotum.

diverted harmlessly into the water bottle. Soon the patient felt relieved of dyspnea, subcutaneous emphysema ceased to spread and then began to disappear very slowly (On the day of discharge it was still slightly present in the scrotum). There were no further excursions of air from the pleural cavity two days after the tube was inserted. This was taken as a sign that either the lung had become adherent to the parietal pleura or that the lacerated visceral pleura had healed and then the tube was removed. Convalescence was only slightly disturbed by the fractured clavicle and ankle. A figure of eight bandage was placed around the shoulders and a circular plaster-of-Paris cast was applied to the leg. The clavicle showed some overriding but healed with excellent functional result. The fractured ankle was in excellent anatomical position and was maintained so. The functional result was perfect.

Primary mediastinal emphysema was seen only twice in our experience, both times in cases of crushing injuries of the entire chest which were severe enough to cause death rapidly.

Mechanism of Subcutaneous Emphysema

Subcutaneous emphysema in traumatic cases may occur (1) with laceration of the chest wall, and (2) with the skin intact

1 With laceration of chest wall

(A) *Without laceration of the lung* The wound may involve all the tissues down to and including the parietal pleura. The arrangement of the muscles, skin, fascia, and parietal pleura may be valve-like, so that air sucked into the pleural cavity from the outside may be forced out of the pleural cavity into the subcutaneous layers of tissue. Muscle may form the valve which prevents egress of air.

(B) *With laceration of lung* Air may also be sucked into the pleural cavity from outside the chest wall. Most frequently little air comes in this manner but rather the air comes from the alveoli or smaller bronchi of the lacerated lung. In this type of case, as in all other types, the diffusion of the air into the subcutaneous tissues depends upon the bicycle-pump activity of the lung.

2 Without laceration of the skin

In this type of case the air must uniformly come from lacerated lung. In most cases the lung will be lacerated by spicules of fractured rib.

Treatment of Subcutaneous Emphysema

Subcutaneous emphysema requires no treatment unless it produces embarrassment of swallowing or breathing. For the case without symptoms, treatment is not only superfluous but may invite infection unnecessarily. In several hundred cases of subcutaneous emphysema observed in

Fig 4 Intercostal drainage tube has been removed after disappearance of the subcutaneous emphysema. (Case 2)

anus is ultimately reached. The course pursued by the infection varies, but usually the tracts pass through the substance of the external sphincter muscle or, in less favorable cases, deep to that structure. With involvement of the sphincters, a painful reflex spasm occurs and this spasm prevents return flow of the pus into the anus. Consequently increasing pressure forces the pus out into the soft perianal tissue and frequently into the ischiorectal fossa. There the real abscess forms. It may form out in the buttocks, the perineum or higher in the pelvis. However, the mode of origin is the same.

The physician usually does not see the patient until after the abscess has developed and frequently not until after rupture has occurred. When the abscess ruptures a fistula exists. If the physician incises and drains the abscess externally, it is a fistula that he has created. This fact should be remembered. In other words, with the appearance of the secondary opening, the fistula is complete. The location of this secondary opening or its manner of development affects neither the diagnosis nor the need for future fistulectomy.

It was once thought that all anal fistulas were caused by tuberculosis invasion of the tissue, few now harbor this notion. One is probably justified in dogmatically stating that, unless tuberculosis exists elsewhere in the body, the abscess or fistula is not of tuberculous origin.

Treatment

As has been suggested, the physician usually first sees the patient after the abscess has developed and frequently after it has ruptured. If induration without fluctuation exists, hot packs should be instituted in an effort to make the abscess "point." Sedatives and hypnotics should not be withheld. If high fever and signs of sepsis are present it occasionally is difficult to decide whether to operate at once or to attempt further localization. No set rule can be established, but in general it is wise to bring the abscess to a head.

Once incision is decided upon a large opening should be created to produce quick and lasting drainage. Exploring the cavity with the finger should be done

gently if at all. No packing is needed. A simple rubber tissue drain may be inserted, hot packs continued, and nothing else done. Roughness in handling or packing may well break down the pyogenic wall and result seriously. The discharge will be profuse for the first few days and then the cavity will begin to shrink and eventually a narrow fibrous tract will remain. Fistulectomy itself is best postponed until true chronicity is evident.

Preparation of patients for rectal operations has probably been too strenuous in the past. No breakfast, cleansing enemas of warm saline, and preliminary narcotics are our only preoperative orders. All rectal surgery on the Proctologic service of the Syracuse University Hospital is performed under transsacral block anesthesia. It offers the advantages of complete relaxation of the anus, absolute safety to the patient, and freedom from distortion of the operative area due to infiltration. We have used this anesthesia in approximately 250 individuals during the sixteen months, from May 1935 to September 1936, with no failures and no untoward results. The technic has been previously described by Lundy who is enthusiastic about its advantages. We also believe that rectal operations are best performed with the patient in the prone position over a "broken table" with the pelvis raised and the head and shoulders lowered. This position gives excellent exposure and allows the surgical assistant to be of real value.

With anesthesia complete, the surgeon first gently dilates the anus and then looks for the primary opening of the fistula. If one notes the position of the secondary or external opening it is possible to judge where in the anal wall the primary opening will be. We have rarely seen described in text books the sensation imparted to the examining finger by a fibrous fistula tract. A cordlike tract can usually be palpated and by following the cord with the finger one can easily determine which direction it pursues into the anal canal. By spreading the anus with a suitable retractor and using a good light a definite sinus can usually be detected. It need not be a large opening. Sometimes a tuft of granulation or a drop of pus will designate the location of the

ANAL ABSCESS AND ANAL FISTULA

Etiology and Treatment

JOHN C M BBUST, M D , *Syracuse*

From Division of Proctology, Syracuse University Hospital

Surgery for the relief of fistula-in-ano dates back into antiquity. Together with trephining we have records of perhaps the earliest operations performed on suffering human beings. History also records that Louis XIV of France was operated upon for fistula and that the surgical fee was the equivalent of \$30,000, apparently proctologists of this twentieth century have fallen upon lean times indeed. Lockhart-Mummery ventures the opinion that more surgical "reputations have been damaged by the unsuccessful treatment of anal fistula than by excision of the rectum or gastroenterostomy."

The lower rectum and anus are the site of many pathologic conditions which, despite their frequency of occurrence are still poorly understood. Anal abscess and its successor, anal fistula, due largely to misconceptions as to their origin, mode of development and treatment, rank high among causes of human suffering.

The term "fistula-in-ano" usually implies a draining sinus on the external skin surface near the anus and another opening inside the anal canal. These have usually been designated as internal and external openings. Buie has long urged that this nomenclature be discarded and that the terms *primary* and *secondary* openings be used. Although the primary opening is always internal, the secondary opening need not be external. Following the initial internal infection, the pus may burrow outside in the usual manner, but occasionally it ruptures back into the rectum or into the bladder or vagina. Such an opening is not external, but it is secondary.

Etiology

An understanding of the etiology necessitates a knowledge of the regional

anatomy. About one to two centimeters inside the anal margin is an anatomic landmark, the dentate or pectinate line. It marks the junction of skin and rectal mucosa. It is irregularly serrated due to the inverted crypts and interposing papillae. These crypts, named by Morgagni, act as potential reservoirs of infection and from these points of infection arise the abscesses and subsequent fistulas. The importance of remembering the crypts as the site of origin cannot be overemphasized. Frequently the physician merely notes the presence of an external sinus. Or, perhaps, if he examines inside he tends to look too high in the rectum for the original opening. One need not look high up. The opening will be found, in practically all instances, at the level of the dentate line in one of the crypts. Failure to find this primary opening usually results in failure to cure the fistula.

Many of the standard surgical textbooks teach that the cause of an anal fistula is an abscess in the ischiorectal fossa. In reality, the abscess is a late stage in the development of the fistula. Again we must look for an offending crypt. Anything that may produce a break in the delicate tissues surrounding these crypts may result in an infection of a crypt and from this in turn the process develops. The infected crypt becomes edematous and the associated papilla becomes inflamed.

This first stage is rarely seen by the physician because the symptoms are not sufficiently severe to alarm the patient. A vague twinge or aching may be experienced, but usually little else. However, as the edema of the crypt increases, the process of burrowing must of necessity start. It is fluid under pressure and naturally the soft tissue adjacent to the

EXTENSIVE PLEXIFORM NEUROMA OF NECK

HERBERT WILLY MEYER, M D, *New York City*

Having had the occasion of seeing a child five years of age, who was kindly referred to me by Dr Spencer Strauss of New York City, with an extensive nevus of the neck and with a large tumor beneath this nevus, the occasion gave us an opportunity to look into the interesting subject of melanomas. This child was born with the pigmented nevus which was located in an area supplied by the second cervical dermatome and the tumor as well as the nevus extended over areas supplied by this second dermatome. The mother first noted the growth under the nevus when the child was two years old and was told that the swelling was a gland. Over the past two and one-half years the growth enlarged slowly, and the mother was advised by various clinics to leave it alone. In the last six months the growth had extended into the ear, onto the cheek, onto the chin, and down onto the chest. One could feel underneath the skin wormlike nodules scattered over the entire left half of the neck, in the ear, cheek, chin, across the midline, and down on to the chest (Fig 1).

In order to arrive at a definite diagnosis a biopsy was first done in October 1935 at the Lenox Hill Hospital where the child was admitted to the Surgical Service of Dr Carl Eggers. The report from the Pathological Department of the portion of the tumor removed showed that it was a typical plexiform neuroma with marked degeneration in the nerve tissue elements. A microphotograph (Fig 2) is hereby appended to show the different types of cells. Three weeks after the first biopsy operation a radical extirpation of the tumor was done. Avertin anesthesia supplemented by inhalation was used. A long incision was made from just below the ear, along the sternocleidomastoid muscle, and down onto the chest. A transverse incision from the midline backward onto the trapezius border was placed at the level of the thyroid cartilage and crossed the

previous incision. The four skin flaps were then carefully dissected backward, opening up a large area, and exposing the tumor over its entire extent. The skin flaps were dissected well up onto the chin, into the lower lip, and high up on to the cheek. A second incision was made overlying the tumor in the ear lobe and the tumor dissected free from its adherence to the skin of the ear and underlying cartilage. A portion of the cartilage itself in the ear was removed. This ear portion was then dropped under the skin into the neck wound. The tumor was found to be densely adherent to the skin itself from which it had to be separated by sharp dissection, showing that the tumor was adherent to the skin which was the site of the nevus. After dissecting the tumor from the cheek and lip down below the lower border of the mandible and from the midline backward it was found that it could easily be separated from the carotid sheath. From here it

Fig 1 Diffuse tumor of left side of neck, ear, and cheek with overlying pigmented nevus

Read before the New York Surgical Society, April 22, 1936

opening It may, however, be scarred over and apparently obliterated But it is always present, and can nearly always be easily found A flexible silver wire probe passed into the diseased crypt will usually enter the opening and the incision should begin from this point It is rarely necessary to begin cutting down from the secondary opening The use of staining solutions or bismuth paste seems unnecessary Such solutions may fail to enter all of the tracts and frequently fail to enter the rectum due to scarring Consequently depending upon them as the guide is dangerous and may result in an incomplete excision The appearance of an incised fistula tract is quite characteristic and no dye is needed The incision once started should be advanced outwardly along the tract in a methodical, cautious fashion All tissue external to the tract should be incised including, if necessary, any or all of the fibers of the external sphincter The tract and all subsidiary tracts should be opened throughout their entire length and all overhanging edges widely cut away One may "freshen" the base of the tract by rubbing with dry gauze This promotes subsequent granulation and aids in seeking side channels In general, any attempt at closure of the wound is unwise since to do so promotes infection and invariably tends to form pockets What is desired is a flat, shallow, accessible wound that can be easily inspected and treated postoperatively

Postoperative Care

Unless a surgeon is willing to personally institute daily postoperative care he should expect only indifferent results At the conclusion of the operation strips of bandage liberally soaked in liquid vaseline may be placed in the wound between the skin edges These should be *entirely* removed at the end of forty-eight hours and from then on no actual packing is required or even desirable Each day the wound edges may be gently separated and a moist cotton swab passed through the entire depth of the wound from the dentate line outwardly Hot wet packs should be applied for the relief of pain and to prevent excessive edema We begin the use of these packs as the anesthetic diminishes in intensity and apply

them continuously for at least the first ten postoperative hours Each day they are used for shorter periods of time By their conscientious use, much pain is avoided and the need for narcotics is lessened

The patient should be instructed in the methods of cleansing the wound after each bowel movement and such a regime of anal hygiene should be followed until healing is complete

It should be emphasized that no packing is required, after forty-eight hours Long fibred cotton may be loosely tucked into the wound and changed as the discharges saturate it Packing and repacking deep in the wound between the cut edges of the sphincter muscle will do much to promote ultimate sphincter incontinence which is naturally the dread of all surgeons

It has been customary from time immemorial for the surgeon to "bind up" the bowels for at least five days and then to administer a drastic purgative Such a procedure seems unreasonable We find that a gentle laxative given on the third evening, followed if necessary by a small enema the fourth morning usually produces a satisfactory and comparatively painless evacuation In fact we do all that is consistent to produce a natural and fairly bulky stool beginning no later than the fourth postoperative day Such a procedure does much to keep the wound dry and free from liquid feces A liberal diet instituted the day after operation will, as a rule, make cathartics or repeated enemas unnecessary

Comment

One point in this brief presentation should be emphasized It may be truthfully stated that once an abscess has formed it is almost always followed by a fistula The very nature and origin of the abscess makes the so-called blind external fistula an impossibility The physician after incising the abscess and thus giving relief should, by all means explain to the patient that an operation for fistula will ultimately be necessary Incising the abscess merely unlocks the tunnel and completes the last stage in the formation of an anal fistula This fact is not sufficiently appreciated by physicians in general

laboratory of a plexiform neuroma and having clinically seen that it apparently arose from the second cervical nerve, mushroomed out and was adherent to the skin which was the site of a nevus, made us look into the question of etiology. In looking through the literature we came across the well-known and excellent article¹ of "Melanoma Studies" as published by Dr. George F. Laidlaw, Department of Surgery, College of Physicians and Surgeons, Columbia University. In this article Dr. Laidlaw and his coworkers brought up the question of the dopa reaction in general pathology.

Bruno Bloch, the distinguished dermatologist of Zurich, noticed the dopa reaction in 1917. It is specific for two kinds of cells, melanoblasts (a term which includes all melanine producing cells as distinguished from nerve phagocytes) and for myelogenous leukocytes (cells which have no known connection with melanine production).

Both of these cells contain coferment, an oxidase, which converts dopa to melanine. This newly-formed melanine colors the cell black and the blackening of the reacting cell is the dopa reaction. Dopa is Bloch's abbreviation of 2, 4, Dioxypyphenylalanin.

The summary of Laidlaw's work shows

1 Bloch's dopa doctrine is introduced as the best working hypothesis of melanine production in the human skin.

2 The dopa reaction is anticipated in the study of pigmented moles, melanomas, and the movement of melanine.

3 In the identification of melanoblasts with the dopa reaction, only positive cells are significant.

4 The appearance of dopa positive dendritic cells in the nonpigmented acanthoses remains unexplained.

5 In the controversies which have arisen over the dopa reaction, Bloch's histological findings are corroborated.

In Laidlaw's articles a simple technic for the dopa reaction is defined.

He further goes into the theory of pigmented moles and their relation to the evolution of hair follicles.

Photomicrographs of silver stained sections are presented to show that pig-

mented moles are rich in nerve fibers and tactile cells. End bulbs of nerve fibers make contact with the nerve cells exactly as they do with tactile cells of the epidermis and of the hair follicles.

In its elevation, pigmentation, nerves, and the groups of tactile cells in the corium the pigmented mole bears a striking resemblance to the tactile spots of the reptiles and amphibia.

In the course of evolution the reptilian tactile spots are replaced by mammalian hair follicles. The pigmented hairy mole seems to be a link or transition from the pigmented tactile organs of the mammalian type. In its hair follicles it is mammalian. In its pigmentation and in its groups of innervated tactile cells in the corium it follows the amphibio-reptilian pattern.

The clinical observation of this patient, showing the neuroma arising from the second cervical dermatone and attached densely to the pigmented nevus of the skin over the distribution of the second dermatone with the excessive growth of hair on the surface of this pigmented nevus, made an exceedingly interesting observation when correlated to the article as written by Dr. Laidlaw which explains so well the findings in this specific case.

It is unfortunate clinically that we did not have a specimen of the overlying skin and tumor which could have been stained for the dopa reaction. It would be interesting and of great value in the future to follow out the studies of Dr. Laidlaw with the dopa reaction in similar cases. We would urgently advise all surgeons interested in melanomas to refer to the original articles of Dr. Laidlaw so that we could all be prepared to follow out these studies in our clinical everyday experiences.

This case is published in the hope that it may be of interest to some surgeons and that it may stimulate the further study of the interesting laboratory findings as published by Dr. Laidlaw.

the supraclavicular fossa and after dissecting the tumor from above down and from below up and from behind forward, it was found that by drawing the sternocleidomastoid muscle forward and exposing the cervical plexus that the tumor itself was densely and firmly adherent to the sheath of the second cervical nerve. The tumor passed upward from here into the jugular fossa and apparently had grown into the jugular foramen from

Fig 4 Healed wound following radical excision

Fig 3 Specimen removed at time of radical excision. Right upper corner, extension into ear, left lower corner, extension onto chest, right lower corner extension towards trapezius

passed along the anterior border of the sternocleidomastoid and was dissected free from the sternocleidomastoid until the posterior border was reached. At this point it dipped down into the posterior cervical triangle. The tumor was then dissected upward from the chest into

which a major portion of the tumor could be teased out, thereby removing this large, plexiform, wormlike mass in one piece. It was freed from the second cervical nerve by sharp dissection (Fig 3). The wound was closed by replacing the skin flaps and suturing with interrupted black silk. Drainage was placed in the posterior cervical triangle and the child made an uneventful recovery (Fig 4).

It is now ten months since the operation and the nevus, of course, is still present, but there is no clinical evidence of a recurrence of the tumor. The prognosis in these cases is, of course, extremely bad and it is to be feared that in the life of this child there will be a recurrence of this tumor.

Once more receiving a report from the

tacks of pain in the right lower quadrant of her abdomen. We saw her a year after the operations still complaining of the same symptoms. Questioning elicited the fact that in addition to constipation, epigastric distress after meals, and poor appetite, she dreaded the cold, was always tired, and suffered from irregular, scant, and painful periods. Basal metabolic rate was minus twenty-nine. Endocrine therapy directed towards thyroid and ovaries relieved her completely.

The second type of abdominal pain resembles that of peptic ulcer or cholecystitis. It is illustrated by one of our patients, a girl of seventeen. She was admitted to the hospital with the diagnosis of subacute cholecystitis but confirmatory evidence was lacking and she was discharged without operation. When seen in the follow-up some months later she gave a history suggestive of attacks of acute appendicitis. This time her appendix was removed which proved to be relatively normal. Her symptoms persisted and then it was noted that she had many of the stigmata of hypothyroidism. Her basal metabolic rate proved to be minus seventeen whereupon she was given endocrine therapy which resulted in complete relief of her symptoms.

Physical examination of these patients is disappointing. In the abdomen, little can be noted except indefinite tenderness and a few gas bubbles. Suspicion is excited, however, by the dry skin, cold extremities, subnormal temperature, and relatively low blood pressure, any or all of which are present. It is also important to note that, contrary to the generally accepted ideas of hypothyroidism, the patient may be thin and restless rather than stout and phlegmatic, the pulse rate is apt to be elevated instead of slow, and the hair may be normal in amount and distribution.

The diagnosis is made in the laboratory by the finding of a low basal metabolic rate and a high blood cholesterol. The determination of the BMR is the test most commonly employed and the average is about minus fifteen. Hurxthal⁶ considers the blood cholesterol a more accurate gauge and in hypothyroidism it will usually be found above 170 mgms per one hundred c.c. of blood.

In the thyroid type of case just dis-

cussed the symptoms are usually chronic. The ovarian type of case, on the other hand, is apt to present subacute or acute symptoms frequently mistaken for appendicitis. The immediate cause of the condition is the rupture of a follicle or corpus luteum cyst with the release of varying amounts of blood into the peritoneal cavity. It was ably described by Novak⁶ in 1917 and has been discussed by many others. Nevertheless, the paper of Hoyt and Meigs⁷ in 1936, indicates that it still remains a cause of many mistaken diagnoses.

The pain is of relatively sudden onset and is situated in the lower abdomen on either or both sides. It is of various degrees of intensity and may be associated with nausea and vomiting. There may be a little fever and leukocytosis and on abdominal palpation tenderness and not infrequently rigidity and rebound tenderness are found.

In differentiating this from appendicitis, there are important considerations in both history and physical examination. A history can generally be obtained of various types of menstrual disturbances and of previous attacks of pain coming at a point midway between the periods or about the time of the period. The association of painful, swollen breasts with menstruation is common. The abdominal pain does not shift from epigastrium to right lower quadrant as in typical appendicitis but begins and remains in the lower abdomen. It tends to diminish and disappear in twelve hours or less. On abdominal examination the point of maximum tenderness is away from McBurney's point and may be on the other side. On vaginal or rectal examination, the tenderness is not necessarily on the right but may be generalized or on the left. Usually no mass can be detected at the time of the acute attack, but if the patient has been examined prior to the attack, a cystic ovary can often be found which reverts to normal size with the onset of the symptoms.

Often the differential diagnosis is extremely difficult. The severe cases with general signs of hemorrhage are almost exactly similar to a ruptured ectopic pregnancy but as both demand prompt surgery this is of academic interest. When appendicitis cannot be definitely excluded

ENDOCRINE DISTURBANCES SIMULATING SURGICAL CONDITIONS OF THE ABDOMEN

CHARLES W. LESTER, M.D., F.A.C.S., *New York City*

From the surgical service of the Fifth Avenue Hospital, Frederic W. Bancroft, M.D., Director

In a recent study of so-called chronic appendicitis¹ in which special attention was paid to the unsatisfactory results, it was found that an appreciable number of the failures was due to the faulty diagnosis of certain endocrine disorders. This stimulated a further study of cases in a general surgical service, the thyroid and gynecological clinics and private practice, and twenty-five cases were found showing abdominal symptoms, apparently of a surgical nature but actually due to faulty endocrine secretion. They represent relatively common conditions which are but poorly recognized, although various investigators have discussed many of their phases.

The patients complain of abdominal symptoms which may be chronic, sub-acute or acute and are confused with surgical conditions, chiefly of the abdomen or pelvis. The glands of internal secretion involved are the thyroid and ovaries although future research may show that the pituitary as the activator of these glands is the basic cause of the trouble. Many women show symptoms referable to both thyroid and ovaries but, for the most part, the symptoms are dominated by one or the other and for purposes of description the cases will be divided into thyroid and ovarian types.

In the thyroid group, the trouble is due to an insufficient secretion. Brown² noted the tendency to constipation with hypothyroidism and subsequently Hinton^{3,4} reported a series of cases of hypothyroidism associated with symptoms of peptic ulcer. Our cases had examples of both types of digestive disturbances and, in addition, showed the general evidences of insufficient thyroid secretion. An understanding of these general symptoms is essential.

The usual concept of hypothyroidism is myxedema but this is an advanced stage

of the condition which is easily recognized. The cases under discussion seldom reach that stage but they do present characteristic symptoms.

Outstanding among these are an intolerance to cold, scanty perspiration, and lassitude. The patients dread cold weather and thoroughly enjoy the heat of summer. They feel tired all the time in spite of more than the average amount of sleep and possibly because of this they are irritable and lack emotional control. They have poor appetites and frequently complain of constipation and "indigestion" but do not lose weight although they are not necessarily overweight. Sexually they have diminished libido and potentia and the women are prone to miscarry. Nearly all the women show some menstrual disturbances, mainly in the form of painful, delayed, and scanty periods and the onset of menstrual life is usually later than the average. The particular type of menstrual disorder is not of diagnostic importance.

The history of these general symptoms must be obtained by questioning as they are of such long-standing that the patients do not think to volunteer the information. The thing that brings them to the physician is abdominal pain and this of two types or a combination of both.

The first and most usual is an inconstant dull pain in the lower abdomen, more often on the right than on the left. Its duration varies from a few hours to several days and many women complain of it prior to their periods. With it is often associated some form of gastric disturbance and constipation, thus making a symptom complex interpreted as chronic appendicitis.

A typical example is the case of a woman of twenty-six who had undergone appendectomy and dilation of her right ureter in another hospital for at-

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M.D., DR.PH., *New York City*

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine

Twitch

A man of thirty-five has a twitch of the right eye for the last three years. It involves his entire right cheek and never leaves him except when he is distracted or when his mind is strongly concentrated upon anything that interests him intensely. Of course, it is completely absent during sleep. There is nothing extraordinary in that. It is the usual, well-known unilateral facial tic.

He had it for a short while in childhood, at about the age of eleven, apparently acquired by imitating his school teacher. But his mother, a devout Catholic, has caused it "to disappear by novenas."

Why has it returned after such a long time? And what is its etiology?

The physical, including the neurological, examination is entirely negative. There is no mental disturbance whatsoever. But the condition itself is of mental origin. It is a reaction to something powerful that has had a deep effect upon this man's life, his feelings, his pride—something that has deranged his plans and has bewildered him.

He used to have frequent quarrels with his wife, but he loved her much and he

thought that she loved him. He believed she was fully adjusted to these scenes and she could stand them without much ado. He never expected any further consequences from these fights, which he, much older than his spouse, usually started and finished.

One day, however, as a culmination of one very unfriendly remark made by him, she took the child and left the house never to come back. That happened three years ago.

The shock for him was great. He took to drink and had brawls with other men. And he noticed his present defect a few days after his wife's departure.

It is very difficult to cure this kind of tic. But to succeed even partly it is necessary to convince the patient of its connection with the sudden and tragic event that has changed his life so much.

That has been done in this case, so far with partial success only. That is, the twitch disappears now for long intervals, but it reappears at the first excitement of any sort.

If there be a moral to this story, the reader must find it himself or herself.

Marriages Are Made in Heaven

It is difficult to say how useful psychoanalysis can be therapeutically, but diagnostically it is certainly a great guide in many cases, if used rationally. Of course, no one need be addicted to it. But stripped of its Talmudic, casuistic, and hairsplitting arguing as done by its overzealous adepts, it is a true philosophy and a necessary chapter in our medical science.

A young physician sent me a case with a story of which he "could make no head nor tail," he wrote.

The woman in question was married several years and had no children. Neither she nor her husband used contraceptives, but

she was never pregnant. They both claimed to be in love with each other. Both desired children, and his genitals and sperm were apparently normal. Her uterus, however, was hypoplastic and less than puerile in development, a condition which none of them knew about and which I was careful not to speak during those critical days.

Lately she had attacks of anxiety during which she cried bitterly or shrieked wildly and was entirely unable to do her housework. The scared husband did not understand her.

In a conversation without any witnesses I attempted to find the reason for her condition, but it was impossible. She seemed

we prefer to operate. This happened in three instances without untoward results and a fourth case escaped operation only because we had previously removed a gangrenous appendix. Indeed, she described her symptoms as another attack of appendicitis.

The pathologic physiology of these endocrine disturbances is still in the realm of theory for the most part. Since the thyroid acts as a general metabolic stimulant affecting glands, muscles, and nerves it seems evident that in hypothyroid states the glands will function sluggishly, the muscles lose their tone, and the nerves become less sensitive to impulses. Applied to the gastrointestinal tract, this condition can be expected to impair digestion and retard peristalsis which in itself will cause some symptoms while others of a reflex nature can arise from distention of cecum and ascending colon.

In the ovarian group, the pain which comes midway between the periods, the mid-menstrual pain or *Mittelschmerz*, can be readily explained by bleeding incident to the rupture of the follicle. When the pain comes later, the rupture of a hemorrhagic corpus luteum cyst is the cause and the severity of the symptoms is proportionate to the amount of bleeding. Novak⁶ has shown that bleeding at the time of follicle rupture is abnormal. Likewise, the failure of the follicle to rupture at the proper time and the development of a hemorrhagic corpus luteum cyst are abnormal. The orderly sequence of follicle development, maturation of ovum and formation of corpus luteum is dependent on hormonal stimulation, probably by the pituitary. Hence, any abnormality of this sequence can be assumed to result from some sort of endocrine imbalance. The exact nature of this abnormality must await future investigations.

While these considerations of endocrine pathology are largely theoretical, they do provide a basis for treatment. Obviously, hypothyroidism requires thyroid medication either in the form of desiccated thyroid or thyroxin. In our experience, the basal metabolic rate is not an exact criterion of the dose required, an observation also made by Kimball.⁸ We prefer to start with a half a grain of desiccated thyroid, U.S.P., twice a day and then to vary the dose to meet the changes in the basal

metabolic rate and the patient's symptoms. We also find that some patients respond better to desiccated thyroid than to thyroxin although why this should be is not clear.

The treatment of the acute condition in the ovarian group is entirely symptomatic although the patients should be under careful observation until the question of some acute surgical condition has been settled. The value of endocrine therapy is in the prevention of future attacks and for this purpose, pregnancy urine extract is employed.

This was first considered an ovarian stimulant of pituitary origin, but later investigation has shown that it comes from the placenta and is probably an ovarian depressant.^{9,10} In either case the action is on the ovaries and it is not a substitution product as is estrin, the use of which is contraindicated.

We administer pregnancy urine extract subcutaneously in five doses of 100 rat units each. The first is given a week after the start of the period, the second, third, and fourth are given on successive days beginning six days later, and the fifth at the end of the third week of the cycle. Thus, the bulk of the medication is given at about the time of ovulation when the pathological condition is assumed to originate. This schedule is adhered to except in those cases with uterine bleeding at two week intervals. It is then impossible to tell which is the menstrual period and the patient is treated by 100 rat units injections on alternate days until the true cycle is determined. Pregnancy urine extract may also be used to supplement thyroid therapy in the hypothyroid cases with marked menstrual disturbances.

Pregnancy urine therapy is not without danger as there have been cases of ovarian degeneration following its excessive use.¹¹ It is wise to discontinue medication after two courses and wait several months before recommencing. Then it is often unnecessary.

Results in the treatment of these endocrine disorders is apt to be slow, especially in the thyroid cases. The prolonged disturbance fosters a neurosis which may need attention after the physical condition has been eliminated. General hygienic measures should also be employed.

Indigent and "Medically Indigent"

While the agitation for compulsory health insurance goes on, those who direct the hue and cry maintain strict silence on the subject of medical care for the indigent. In their determination to establish lay political control over healing, regardless of the consequences to the public health and purse, they willfully neglect any phase of medical care which does not contribute to their ends.

There are three broad aspects to the proper distribution of medical service—care of the self-supporting, care of the needy, and care of that in-between group which is able to provide for ordinary daily needs but cannot maintain its independence in the face of serious or protracted illness. The first class presents no problem to the community. Any attempted solution which fails to take both the other groups into consideration is dangerously incomplete. There can be no real satisfaction of community needs by a system that fails to provide for both the indigent and the "medically indigent."

As in the case of unemployment relief, remedial measures are obstructed by a lack of accurate information as to the number of those requiring aid. Guesses as to the extent of unemployment varied by millions throughout the depression, and to this day no one knows what the

situation really was or is. So there has been no serious attempt to classify the needy and the low income groups requiring assistance in various medical emergencies.

For a number of years the profession has advocated a central bureau for the registration of all requiring free or under-rate medical care. This would not only prevent imposture and wasteful reduplications of service but would furnish an accurate index to the extent of the problem actually confronting the community.

Report of the American Foundation Studies in Government

There will soon be issued the report of the American Foundation Studies in Government. This Foundation made a nation-wide survey, consulting competent medical opinion throughout the country, on the conditions of medical practice—what changes the current era warrants adopting for the delivery of medical care to the American people, and what form such changes, if any, should take.

There was no preconceived idea behind this study. There was an honest effort to find out what the American doctor thought about the questions. Naturally, since it was generally known, the official

to withhold something I made no more headway with her husband alone. Each one of them claimed to be sexually satisfied and happy, but characteristically enough, they both dismissed the subject and tried to change it quickly.

There seemed to be nothing of importance in this patient's childhood and past history that would help to solve the puzzle.

Our sessions yielded no result until one day I questioned her about day-dreaming. Yes, she had semi-visions—imagnations, she called them—and they always turned around the same subject. Very reluctantly and after painful detective work on my side she admitted that she thought herself run over by a heavy truck in the middle of the street. Her legs were torn off, she was in bed, in a hospital, and her husband either could not come to see her or, when allowed to do so, he could greet her from a distance only.

I told her the meaning of this dream and asked her why she did not care to be with her husband. Then only she confessed that he never gratified her, that his emissions were premature and that the intercourse

made her nervous and left her in great despair. But she had never spoken to him about it. In fact, when he, rarely, asked her, she answered that it was all right.

He avowed that since he had given up the hope of having a child his wife did not appeal to him and he had intercourse with her in a perfunctory way, "only for her sake," he said. With another woman whom he saw occasionally he was sexually perfect.

The situation was dangerous for our patient. The revelation about the significance of her day-dreams had no effect whatever, except that she modified them somewhat. None of the psychotherapeutic methods employed in such situations were efficacious. The advice that she go and spend some time with her parents, who were living in a distant town, was eagerly accepted by both. After the time was up they refrained from coming together and now, after five years, they have not met again. The patient is cured, as I learn through correspondence.

Marriages are made in heaven. Is that the reason why they are often failures?

DOCTORS TO HELP PHARMACISTS CLEAN HOUSE

More than 1,000 members of the Consolidated Brooklyn Retail Pharmacists, Inc., closed their stores for four hours recently, picketed seventy-five stores whose proprietors refused to close and met at the Hotel Bossert to take action against unfair trade practices.

They were informed by their president, George Gottesman, that close to seventy per cent of their number were actually insolvent and were staying in business only on the sufferance of drug manufacturers and wholesalers.

They voted to undertake a campaign of education through advertising to acquaint the public with conditions in the drug trade and to expose as far as possible such evils as price-cutting, the use of proprietary and patent medicines in the place of prescriptions and the manner in which competitors were underselling them.

After hearing a physician, Dr. Charles Solomon, chairman of the subcommittee on drugs of the Kings County Medical Society, assert that doctors lacked education in prescribing for patients, they voted to assign a detail of members to visit the physicians of the borough and instruct them.

"Unless you help the medical profession to clear up the patent and proprietary medi-

cine racket you will not receive the aid of the doctors," Dr. Solomon said.

"Doctors today are taught therapeutics daily by men detailed from the drug manufacturers. Young doctors are afraid to write prescriptions because they have never learned how in the medical schools. Doctors are inscribing names, not drugs, on their prescriptions, and it is up to you to help us."

"I want it understood," Dr. Solomon is quoted as saying, "that the pharmacist must stop practicing medicine by his counter prescriptions of patent medicines and the like if he is to receive any respect or support from the medical society. The physician, usually, is not a pharmacist. I dare say that the pharmacist is never a physician, and is no more qualified to prescribe for patients than any other merchant who carries patent medicines on his shelves."

George Gottesman, president of the Consolidated Brooklyn Retail Pharmacists, has given notice that the members of his association have just begun to fight.

He reported that a committee of five pharmacists from Brooklyn will meet a like committee from the Kings County Medical Society to effect co-operation in the drive against proprietary medicines.

recession of the rivers The necessary serums and vaccines are being administered wholesale by groups of physicians who are working without regard for self The sickness of individuals is also being cared for with an efficiency which is little short of remarkable considering the physical condition of the affected areas

The doctors are now as always, contributing their share in work and money and placing their services at the disposal of our people regardless of the sacrifice entailed They never forget their trust!

Telling the World

The past two months have witnessed a nation-wide resurgence of opposition to compulsory sickness insurance As state and county medical societies all over the country have redoubled their efforts to call public attention to the higher costs and lower quality of political medicine, groups that had almost resigned themselves to the socialization of practice have again taken up arms If the laity can be made to realize the destructive influence of this system on health and living standards, the profession will no longer have to bear the brunt of battle alone

The advocates of obligatory sickness insurance do not distinguish themselves by consistency They promise the doctor great benefits under their plan and then attribute his opposition to selfishness There are no such contradictions in the profession's rejection of health insurance It cannot accept facile promises of improved prophylaxis and more efficient distribution of therapeutic services when the morbidity and mortality rates for insured and uninsured countries prove the superiority of private practice It cannot accredit claims of lower costs when administrative expenses consume fifteen cents out of every insurance dollar even in England, where the Civil Service is conceded to be more honest and efficient than our political bureaucracy It cannot believe that physicians would be better off under health insurance when the corres-

pondence columns of British medical journals contain abundant evidences of dissatisfaction Increasing numbers of English panel practitioners are resenting the low pay and long hours, the degrading condition brought about by excessive demands for medication from patients and strict regulation of prescribing by the government, the lack of opportunity for painstaking examination and resultant serious errors in diagnosis

Whenever and wherever medical care is subjected to lay control, however well-intentioned, the quality falls off and costs mount Individual health services belong in the hands of the private practitioner, who has heretofore dispensed them humanely and efficiently, to the glory of medicine and the betterment of the public health Mass health questions demanding governmental intervention should be under the jurisdiction of a medical department exclusively concerned with medical problems The state could make no greater mistake than to relegate the health of its citizens to a subordinate position in a general welfare department administered and controlled by laymen

\$165,000 Grant for More Health Studies

According to a news release from the Foundation on January 23, the Julius Rosenwald Fund has made a grant of \$165,000 over a period of five years to help finance a new Committee on Research in Medical Economics This committee has recently been incorporated in this State Its personnel consists of Michael M Davis as Chairman, Professor Robert E Chaddock, Columbia University, Henry S Dennison of Framingham, Mass, Professor Walton H Hamilton of the Federal Social Security Board, Elvin S Johnson, Director of the New School for Social Research, N Y, Editor Paul U Kellog of the *Survey Graphic*, N Y, Professor Harry A Millis, University of Chicago, Mr Fred M Stein, a banker of New York

attitude of organized medicine was not sought, but many prominent medical men connected officially with various units of organized medicine were individually consulted and gave aid and furnished their individual opinions which are incorporated in the report.

Our Committee on Trends, in a recent release through the Public Relations Bureau, is of the opinion that the forthcoming Report will tend to stress the divergence of opinion among medical men in regard to the topics under inquiry, and prophesies that this very divergence of opinion will be seized upon by the "socializers" in Washington to foist their pre-conceived schemes upon us. The warning of our Committee on Trends should put us all on guard against the utilization of this factor by outsiders. Of course, doctors being individualists, and each acting for himself, set about to answer the inquiry as he thought best, from his own angle of observations, and with no thought for concerted action. Hence, the usual compromises in details not having been made, it seemingly may uncover an apparently large diversity of opinion.

In view of the fact, however, that a great cross-section of the medical profession will have registered its own views and own ideas, would it not seem wise on the part of organized medicine to study the report with the particular end in view of evolving from it *common factors* which can be incorporated *now* into some practical suggestions to government agencies to take the burden of carrying the entire costs of medical care to the indigents from off the shoulders of the medical profession, and also of developing means to overcome the handicap imposed by financial barriers toward bringing adequate and high quality medical care to the underprivileged classes? Incidentally, if we can find common ground in all the communications from professional men, to meet hospital problems, to bring diagnostic aids to communities now unprovided with them, and to extend the reaches of preventive medicine, we desire to be the first to greet such practical

suggestions for making these measures effectively operative. No matter how much diversity of opinion there is additionally to be found in the report, the common ground should be the objective of our studious scrutiny.

The forthcoming report is the first survey made by an extra-medical body which has exclusively consulted medical opinion on the mooted questions at issue. As such, it is indeed welcome, and while we grant that to the casual observer the diversity of opinion may at first seem confusing, we feel that the more the report is studied, the more there will be found of common ground among the professional opinions expressed. For medical men have been trained in a tradition which values quality of service, over quantity and cheapness of service. They have always sought means to extend preventive medicine, and they now sense a trend of the times which makes most of us believe that the opportunity is open to the organized profession to make its own contribution toward the solution of these problems. Until now, it was the "socializers" and other outsiders who made the propositions which, when weighed in the balance, were found wanting. Our opportunity is now. Study the Report, it was written by your colleagues. Then let us act. Informed public opinion expects no less than that of us.

The Flood

The great catastrophe which has been visited upon the inhabitants of the Ohio Valley and which threatens those who live in the vicinity of the Mississippi is leaving in its wake a sorrowful spectacle of ruin and wreckage. The intense suffering, the loss of property and home are only equalled by the fear of disease.

All public health agencies are united in their efforts to avert the outbreak of epidemics which might result from the infected waters and unsanitary conditions that at present exist, and for which time will be required to correct following the

CURRENT COMMENT

Benzidrene

This drug is a synthetic one (beta-phenyl-isopropylamine), chemically like epinephrine and ephedrine. It was originally introduced for topical use in shrinking the nasal mucosa, but further experience has shown that its action is not limited to this alone. Experimental animals put into a narcotic sleep by barbitone were awakened following administration of benzidrene. When given to humans, it has a marked stimulating effect upon the cerebral function, inducing sleeplessness, exhilaration, and an increase in the intellect. Mental fatigue is replaced by clarity of thought and self-assuredness.^{1 2}

Roentgenologists have reported that benzidrene is distinctly useful for the relaxation of gastrointestinal spasm.³ Its effect upon the blood pressure has also been studied and it was found that a maximum rise is attained at the end of one to two hours with a gradual return to normal within eight hours following oral administration.⁴ But the full pharmacology of this drug remains to be determined. The desirable effects reported are balanced by untoward results such as marked polycythemia following prolonged use, an impairment of the appetite and symptoms of cardiovascular disturbances. Promising as are the beneficial effects obtained from the employment of benzidrene in internal therapy, its indiscriminate use is to be cautioned against at this time. More experimental and especially clinical data must be forthcoming before the limits of safety are fully comprehended.

CURRENT COMMENT

"IT IS NO SECRET THAT GRAFT, incompetence, bureaucracy, red tape and patronage have been realities in American Government. Unless these can be brought well under control they may devour more than does all

the waste of exploitation and abuse in the private industry, serious as that is. (We should recognize, however, that it is not only government which suffers from internal politics. Most of the great power combinations are less than twenty-five years old, yet I suspect that few of them are free from the problem of bureaucracy, nepotism, and patronage which tend to go with bigness, either public or private.)"—An excerpt from a news release by Arthur E. Morgan, Chairman of the Tennessee Valley Authority, in the *New York Times* of Sunday, January 17

"ADMIT THAT OUR SYSTEM of medical practice has its shortcomings, it is still the best ever devised. Admit that American medical education and practice were backward and benighted for the first century of our national existence. That was Osler's plaint when he first came to Philadelphia from McGill. Yet, in the past sixty years American medicine has developed an efficiency and excellence that now attracts students and medical men from the four corners of the earth. The Mecca is here, and the trek is on. And it all came about in a democracy where private practice prevailed and ambition spurred the physician to his best efforts."—From the *Milwaukee Medical Society Bulletin*

"SCIENCE ANNOUNCES THAT IT IS A STEP nearer solving the problem of how to pre-terminate the sex of offspring. This is one goal which we hope science will never reach. We can imagine few things more disastrous, in the long run, than to put into human hands the power to make every firstborn child a boy."—Just an opinion voiced by the editors of *Today*

Raymond Moley, in the same publication but in a more serious mood, states that "Granted that we cannot survive without more security and economic equality for the majority of our people, yet how much security and 'leveling up' can the nation afford to pay for? * * * The basic problem is clear-cut: we cannot have every form of security and standardization and every form of freedom, for every new item of security and 'leveling up' we take on, we shall have to give up a degree of freedom * * *"

CLAIMS LADY NANCY ASTOR, "In England three pounds out of every five pounds of an individual's income-tax goes to social security taxation"

¹ Primmetal and Bloomberg *J.A.M.A.* 105 2051 1935
² Peoples and Guttman *Lancet*, 1 1107 1936
³ Myerson and Ritvo *J.A.M.A.* 107 24, 1936
⁴ Myerson, Loman and Dameshek *Am J Med Sci* p 560, October 1936

There is also the inevitable Medical Advisory Board, to be enlarged as required¹ The following physicians are *now* members of this board Dr Samuel Bradbury of Philadelphia, Dr Alfred E Cohn of New York City, Dr Alice Hamilton of Washington, Dr Ludwig Hektoen of Chicago, Dr Franklin C McLean of Chicago

Most all of those on the active committee, particularly its chairman, Michael M Davis, and Mr Walton H Hamilton, are very strong proponents of compulsory health insurance, and during recent years have bent every effort and used every means available to them to foist this foreign scheme upon American medicine and upon the unwary laboring classes and the tax-paying public No valid arguments advanced by any source authoritative enough to have considered opinions has served to stop these men in their endeavors to reach their preconceived goal Of the medical group which makes up the medical advisory board, most of them are not engaged in the private practice of medicine They have little experience and small knowledge or sympathy with it It is not unreasonable to suppose that being unsympathetic to it, they would have little hesitancy in helping to destroy it

The creation of this new set-up seems to be the final gesture in the field of medical social endeavors of the Julius Rosenwald Fund The Fund states that since 1928 it "has been actively at work with the aim of reducing the costs of medical service"—(*It seems strangely unconcerned with the quality of the cheapened service it seeks to promote*),—"and of making them more accessible to people of small incomes" (*Totally unconcerned whether or not they reduce the American living standards thereby*) "Now the organized medical profession, hospitals and many industrial and governmental agencies are engaged in practical experiments in different parts of the country, organizing medical care to reduce costs or developing methods of getting these costs into the family budget Hence there is *now less need for the promotion of action*

than for the guidance of action through scientific and dispassionate studies" (Parentheses and italics ours)

For the cessation of propagandist activity and for its public announcement the medical profession is of course duly grateful to the Fund Perhaps, the Fund has learned the actual truth about compulsory health insurance We at least hope so We also wonder, as does the *New York Medical Week* what new achievements are to be expected from the new committee and its hand picked medical advisory board We are somewhat astonished to find Dr Alfred E Cohn of the Rockefeller Institute staff on this board—for heretofore no one connected with the staffs of the various Rockefeller Funds or Foundation has taken any active part, even indirectly toward influencing legislative enactments, and we should exceedingly regret noting a new trend in the working of this great and useful Foundation

We also are pondering how men who have actively agitated for legislative enactments in state and nation and backed bills introduced in legislatures to accomplish their set purposes in regard to foisting compulsory health insurance upon us,—how these men, at this stage, and in these times, can accept money grants to make a five year study of something upon which their minds are apparently made up, and upon which they seem in accord If the problem is still so vague to them that so much money, and at least five years time for study is necessary, how do they explain their enthusiastic public endorsements of the last few years Now these active propagandists for adoption of uncompleted and unfinished studies, want five more years for study, and they accept the neat little sum of \$165,000 to do it When this sum is exhausted, and if meanwhile their preconceived goal is still unattained, we doubt not, that more money and further committeeships will eventuate¹

"The world is grown so bad,
That wrens make prey where eagles dare
not perch"

Inquiry On The "Safe Period"

To the Editor

In line with out interest in "medical aspects of human fertility," we are impressed by the extensive and increasing interest in and reliance upon the so-called "safe period" as a means of contraception. There is urgent need for determining, as accurately as possible, whether there exists, for the regularly menstruating woman, a predictable and reliable moiety of her cycle in which fertilization is impossible. The National Committee on Maternal Health is undertaking to collect pertinent data which, by reason of their source, will be of exceptional value.

We seek to enlist specially qualified married couples who will scrupulously keep and transmit to us—confidentially, of course—accurate and complete records of menstruation and coitus over a long period of time, several years if possible. We suggest, though not exclusively, couples of whom one or both are, say, physicians or graduate students or faculty members or research workers in biologic or other scientific departments, therefore competent to furnish trustworthy records and also scientifically interested in contributing to this investigation.

A couple such as we wish to enlist would prefer not to have a pregnancy develop during the next year or more, although if one did develop it would not be calamitous. Accordingly, the couple would observe the so-called "safe periods" as their sole means of avoiding conception. If that succeeds, and then the time comes when they desire

a child, they would reverse their practice, confining coitus to occasions outside the "safe period," or they would at least restrict intercourse to the moieties of the menstrual cycle when, theoretically, pregnancy is most likely to result, and then record how soon it does result. Needless to say, there must be no known or probable factor of involuntary sterility in either one of the couple.

The frankly experimental character of the coital practices on which these records are based, and the special qualifications of the recorders, will make these data uniquely valuable.

The committee is peculiarly fitted to collect these records. Its territory is large enough to encompass couples in numbers adequate for the investigation—couples who, by reason of their particular qualifications and their willingness to volunteer, must be few in any one community, no matter how large the latter may be.

On application, we shall distribute to individuals simple record forms and brief instructions easy to follow. We hope to hear from as many as possible who are reached, directly or indirectly, by this announcement. Please address National Committee on Maternal Health, Inc., New York Academy of Medicine Building, 2 East 103 Street, New York, N. Y.

RAYMOND SQUIER, M.D.

Maternal Health Inc.*

January 25, 1937

TO STUDY AFRICAN LEPROSY

Dr Victor G. Heiser, author of "An American Doctor's Odyssey," president of the International Leprosy Association and a pioneer in the investigation of leprosy for more than thirty years, has sailed to study the disease in Central Africa, where it is believed to manifest itself in a form not

found elsewhere.

Dr Heiser said that the disease in the region he will visit was of the tuberculoid leprosy type and he was particularly eager to investigate its origin and transmission. The British Government has asked him to report to it on his findings.

"LET US BEWARE LEST IN our desire to be kind to the weaker brethren of today we are not more than unkind to all the brethren of tomorrow"—A warning from the pen of Lord Dawson, and transmitted to us by the London correspondent to the *JAMA* of January 23

"CONGRESS PROBABLY WILL enact a new Food and Drug Act though it will lack the teeth of last year's unsuccessful bill. One of the old disputes which was whether the Federal Trade Commission or the Food and Drug Administration shall control advertising, has been settled. The Drug Administration won out"—A forecast and a statement by the editors of *Today* in their issue of January 30

"FREE CARE TO THE INDIGENT is admittedly one of the foundation stones of education in medical-college hospitals and clinics. But we are inclined to doubt the opinion held in some quarters that full-fledged physicians are recompensed for their charity services merely by the added training they receive. It could be as apt to maintain that, for no reward other than the skill derived from their efforts, engineers should build bridges, lawyers, win suits, teachers, educate, or bankers, lend money"—Another angle on the question presented by William Alan Richardson, in *Medical Economics* for January 1937

"As ITS FINAL GESTURE in the field of

medical service, the Julius Rosenwald Fund has announced a grant of \$165,000 for another five year study of medical economics. The research Committee which will conduct the projected survey is headed by Michael M. Davis and includes such other 'impartial' investigators as Walton H. Hamilton and the editor of the *Survey Graphic*

"For a number of years past the men referred to have been outspoken advocates of compulsory health insurance. Now, it appears, they require another five years for further 'studies in the economic and social aspects of medical care.' Apparently the method is to arrive at conclusions first and then investigate—a procedure somewhat too reminiscent of 'Alice in Wonderland.' If these supposed experts consider five more years of research necessary, the time has certainly not yet arrived for legislative endorsement of obligatory pre-payment.

"The medical profession cannot help wondering what new achievements are to be expected from a program of this type. It is not very long since the Committee on Costs of Medical Care spent five years and over a million dollars on a similar study. Now another five year project is to be launched by the same sort of group. In law, if previous experience arouses a suspicion of prejudice, a 'change of venue' may be sought. In this case, a change of personnel is strongly indicated if unbiased conclusions are desired. No group can be designated a 'committee on research' that is as strongly dominated by a preconceived idea as this one"—From the *New York Medical Week* of January 30

POEM OF THE DAY

Observed by E. V. W. in the Baltimore Sun during meeting of the Southern Medical Association and reprinted in the *AMA Journal*

PATIENCE PATIENTS!
OR
THE DOCTOR LOOKS AT WEDNESDAY
THURSDAY AND FRIDAY

"Oh, Doctor, please come. I've a pain in my 'tum, and my throat feels a little bit rough."

"What? I'm off to Convention. Such trifles don't mention—your illness is not rare enough."

Unless you've thrombosis, a touch of sclerosis, a disease that, at least, is mysterious,

A call I've no time for, no reason nor rhyme for—don't 'phone till you find you're delirious

We've a lengthy discussion on 'Brain and Concussion' I'd really be quite out of humor

If called for arthritis, or conjunctivitis, or anything short of a tumor!"

In the Armory Hall (it's not open to all) there's a series of gruesome exhibits

But the layman turns green, and it's clear to be seen he soon loses his yearning to kibitz

So this week, if you please, do not yield to disease, to symptoms refrain from attention,

The Doctor can't come for a look at your 'tum—he's attending the blasted Convention!

AMY F GREIF

sisting of the President of the Society and four Presidents of District Branches, as provided in the By-Laws

Article VII

Meetings

There shall be an annual meeting of the Society and of the House of Delegates to be held at a time and place designated by the House of Delegates

Article VIII

Funds

Funds shall be raised by an annual per capita assessment on each component County Society at a uniform per capita rate throughout the State. Funds may also be raised in any other manner approved by the House of Delegates or by the Council of Trustees when the said House of Delegates shall not be in session.

The approval of the Council of Trustees shall be necessary for the expenditure of any funds of the Society

Article IX

Referendum

At any meeting of the House of Delegates a majority of the members present may order a referendum vote of the Society on any question consistent with the Constitution and By-Laws and in accordance with such regulations respecting the submission of the question as the House of Delegates may prescribe. The members shall vote thereon by mail. The polls shall be closed at the expiration of fifteen days after the mailing of the question, and if the members voting shall comprise a majority of all the active members of the Society, a majority of such vote shall determine the question and be binding on the Society and the House of Delegates. The Council of Trustees may, in a similar manner, order a referendum to the House of Delegates

Article X

District Branches

Sec 1 The membership of the Society shall be divided into eight District Branches, as follows

The First District Branch shall comprise the members of the Medical Societies of the Coun-

ties of New York, Bronx, Westchester, Rockland, Dutchess, Putnam, Orange, and Richmond

The Second District Branch shall comprise the members of the Medical Societies of the Counties of Kings, Queens, Nassau, and Suffolk.

The Third District Branch shall comprise the members of the Medical Societies of the Counties of Albany, Rensselaer, Schoharie, Greene, Columbia, Ulster, and Sullivan.

The Fourth District Branch shall comprise the members of Medical Societies of the Counties of St Lawrence, Franklin, Clinton, Essex, Hamilton, Fulton, Montgomery, Schenectady, Saratoga, Warren, and Washington

The Fifth District Branch shall comprise the members of the Medical Societies of the Counties of Onondaga, Oneida, Herkimer, Oswego, Lewis, Madison, and Jefferson

The Sixth District Branch shall comprise the members of the Medical Societies of the Counties of Otsego, Delaware, Chenango, Cortland, Tompkins, Schuyler, Chemung, Tioga, and Broome.

The Seventh District Branch shall comprise the members of the Medical Societies of the Counties of Monroe, Wayne, Cayuga, Seneca, Yates, Ontario, Steuben, and Livingston

The Eighth District Branch shall comprise the members of the Medical Societies of the Counties of Erie, Niagara, Orleans, Genesee, Wyoming, Allegany, Cattaraugus, and Chautauqua

Sec. 2 Each District Branch may adopt a constitution and by-laws for its government and may amend the same, but before becoming effective they shall be approved by the Council of Trustees. They shall be consistent with the Constitution and By-Laws of this Society

Sec 3 Changes in the number or membership of these District Branches may be made by a two-thirds vote of the House of Delegates at any annual meeting

Article XI

County Societies

The terms County Medical Society or component County Medical Society shall include all County Medical Societies now in affiliation with this Society or which may hereafter be organized and chartered by the House of Delegates. There shall be but one County Medical Society in each County affiliated with this Society. If there should be an insufficient number of physicians in any of the Counties of this State to form themselves into a component County Medical

COMMITTEE ON REVISION OF CONSTITUTION AND BY-LAWS

The Committee on Revision of the Constitution and By-Laws herewith presents a first draft of its report. It is published to acquaint the members with the proposed changes, and to invite comment and constructive suggestions, all of which will be carefully considered. The Committee wishes to reiterate that this is not necessarily the form in which its final report will be submitted to the House of Delegates, and reserves the right to make minor alterations, or even changes in principle, if these are deemed expedient. Society Members are requested to address all communications to the Chairman of the Committee, O W H MITCHELL, College of Medicine, 307 So McBride St., Syracuse, N Y

Constitution

Article I

Name and Purposes

The name and title of the Society shall be the Medical Society of the State of New York. The purposes of the Society shall be to federate and bring into one compact organization the medical profession of the State of New York, to extend medical knowledge and advance medical science, to elevate the standard of medical education, to secure the enactment and enforcement of just medical and public health laws, to promote friendly intercourse among physicians, to safeguard the professional and economic integrity of its members and to establish and maintain them in appropriate and equitable relationship with the public, with government and with all agencies working in the fields of health and welfare, and to enlighten and direct public opinion in regard to the problems of medicine and health for the best interests of the people of the State.

Article II

Membership

The membership in this Society shall be divided into three classes: (a) Active (b) Retired (c) Honorary.

Article III

House of Delegates

There shall be a House of Delegates which shall be the legislative body of the Society and shall be charged with the general management, superintendence, and control of the Society and its affairs and shall have such general powers as may necessarily be incident thereto, except as otherwise specifically provided by the Constitution and By-Laws. It shall pass upon the credentials and qualifications of delegates and shall

decide who are entitled to be members of the House of Delegates. It shall have authority and power to suspend or otherwise discipline its own members, District Branches, component County Medical Societies or any member of the Society charged with special duties for and under authority of the State Society. It shall provide for a division of the scientific work of the Society into appropriate sections, for the organization of the District Branches, for rules and regulations for its own government and for the administration of the affairs of the Society. When the House of Delegates is not in session, the Council of Trustees shall exercise all the rights and duties of the House of Delegates that are not inconsistent with the Constitution and By-Laws of the Society. (See By-Laws)

Article IV

Council of Trustees

There shall be a Council of Trustees composed of the President, the President-Elect, the immediate Past-President, the Treasurer, and fifteen other members elected by the House of Delegates.

Article V

Officers

The officers of the Society shall be a President, a President-Elect who shall serve as first Vice-President, a second Vice-President, a Treasurer, an Assistant Treasurer, a Speaker, and a Vice-Speaker of the House of Delegates. They shall take office at the termination of the annual meeting at which they were elected.

Article VI

Board of Censors

There shall be a Board of Censors con-

nently disabled may *ipso facto* have the privilege of applying for retired membership in the State Society. All such applications shall be signed by the President and the Secretary of the County Society of the applicant and then sent to the Secretary of this Society for presentation to the House of Delegates for approval. Active members desiring to become retired members shall apply for such membership to the component County Society in the County of the residence of the applicant. Such applications shall be governed by the Constitution and By-Laws of the Component County Society relative to active membership. Retired members shall not be subject to assessment, but shall be accorded all the rights and privileges of active membership except voting and holding office.

Sec. 7 The honorary members of the Society shall be all persons now on the roster as such and in addition such distinguished physicians residing outside of the State of New York as may hereafter be elected. All nominations for honorary membership must be endorsed by three members of the Society and forwarded to the Secretary for presentation to the House of Delegates, which by a two-thirds vote of the House of Delegates present and voting shall be declared elected honorary members of this Society. Honorary members shall be entitled only to the privilege of attending and addressing the meetings of the Society.

Chapter II

House of Delegates

Sec. 1 The House of Delegates shall be composed of (a) Delegates elected by the component County Medical Societies, (b) Officers of the Society and other Members of the Council of Trustees, and (c) the President of the District Branches sitting as District Delegates. Past Presidents of the Society shall be life members of the House of Delegates with voice but without vote. Each component County Society shall be entitled to elect as many delegates as there shall be State Assembly Districts in such County at the time of the election, but each component County Medical Society shall be entitled to elect at least one delegate. A component Society representing by its name more than one County shall be entitled to as many delegates as there are

Assembly Districts in the Counties named in the title of such Society.

Sec. 2 A delegate to this Society shall not be considered in good standing or entitled to vote in the House of Delegates if the component County Medical Society by which he was elected is in default of the payment of any dues or assessments imposed by the House of Delegates, and said County Society has been duly notified of such default, or if such component County Medical Society shall at the time be under sentence of suspension imposed by the House of Delegates, or if such delegate is not in good standing in this Society, or in the component County Medical Society to which he belongs. The term of a delegate elected by a County Medical Society shall begin at the first annual meeting of the House of Delegates subsequent to his election.

Sec. 3 The annual meeting of the House of Delegates shall be held on the day before the annual meeting of the Society. The sessions of the House of Delegates may be adjourned from time to time as may be necessary.

Sec. 4 A quorum shall consist of sixty duly elected or constituted members of the House of Delegates.

Sec. 5 The House of Delegates shall hear and finally determine all appeals taken from decisions of the Board of Censors.

Sec. 6 The House of Delegates shall provide for the issue of charters to County Societies in affiliation with this Society.

Sec. 7 The House of Delegates shall have authority to appoint special committees from among members of this Society.

Sec. 8 The following shall be the order of business at the sessions of the House of Delegates:

- 1 Calling the meeting to order
- 2 Report of Reference Committee on Credentials
- 3 Roll call by the Secretary
- 4 Reading the minutes of the previous meeting
- 5 Report of the President
- 6 Address by the President-Elect.
- 7 Report of the Board of Censors
- 8 Report of the Council of Trustees
- 9 Report of the Secretary
- 10 Report of the Treasurer
- 11 Reports of District Branches by District Delegates
- 12 Reports of Special Committees
- 13 Reports of Reference Committee

Society, such physicians may become members of the component County Medical Society of an adjoining County when eligible by the Constitution and By-Laws of such County Society

Article XII

Amendments

Amendments to this Constitution, except such as are obligatory by law, shall be made only at an annual meeting of the House of Delegates Notice of the proposed amend-

ment shall be given at a previous annual meeting of the House of Delegates, and before the same can be acted upon, it shall be published at least once and at least one month before the annual meeting in the official publication of the Society

A two-thirds vote of the members of the House of Delegates present and voting shall be necessary for adoption

Amendments made necessary by law shall be made either by the Council of Trustees or House of Delegates whenever such necessity exists

BY-LAWS

Chapter I

Membership

Sec 1 The active members shall be all active members in good standing of the component County Medical Societies A copy of the roster of such members, certified to be correct by the Secretary of such County Society shall be evidence of the right of the members whose names appear therein to membership in this Society No member who has been dropped from the roll of a component County Society by reason of failure to pay dues shall be accepted by another Society except by regular transfer after reinstatement in the original Society

Sec 2 The term "good standing" is hereby defined as (a) A member is in good standing when his dues to his County Society and the assessment of the State Society have been paid when they are due and payable (b) A member whose dues and assessments are unpaid after May 31 of any current year, is not in good standing He is in arrears for dues He has lost his right to malpractice defense by counsel of the Medical Society of the State of New York for any acts upon which suit may be predicated during the period of his arrearage This last is not recoverable, even when he becomes reinstated Immediately upon payment of dues during the current year, his right to malpractice defense by counsel of the Medical Society of the State of New York shall be restored from that date (c) A member whose dues and assessment are unpaid after December 31 of any current year shall automatically be dropped from the rolls of membership of both County and

State Societies, without notice to such member by his County Medical Society or the Medical Society of the State of New York, or without further action on the part of either County or State Society, and upon such date, he shall automatically cease to be a member of both County and State Societies

Sec 3 Any member expelled from his component County Society or suspended from its rights and privileges, shall likewise be expelled or suspended for the same period from this Society The right of appeal to this Society shall not be impaired, nor shall such appeal prevent the carrying out of the judgment of the County Society pending such appeal Members not in good standing or ceasing to be members of their County Societies, shall *ipso facto* have the same status in this Society Suspension or expulsion shall terminate malpractice defense and automatically cancel the Society's malpractice insurance

Sec 4 A member of one County Society shall not be permitted to transfer to membership in another County Society until he has established a legal residence in the County to which he desires transfer The question of legal residence shall be verified by the Board of Censors of the County Medical Society to which the member desires transfer

Sec 5 Any member convicted in a court of law of a crime evincing moral turpitude shall thereupon cease to be a member of this Society

Sec 6 A member in good standing in his component County Medical Society, reaching seventy years of age or if perma-

of Delegates The Council of Trustees shall have power and authority to employ, discharge, arrange duties and fix compensation of and for any employee which it may find necessary for conducting the affairs of the Society

Sec. 2 The Council of Trustees shall meet at the close of the annual meeting of the House of Delegates The members of the Council of Trustees shall hold office until their successors are duly elected and qualified.

Sec. 3 It shall meet at regular intervals at times and places that shall be fixed by the Chairman Any four members of the Council of Trustees may require the Chairman thereof to call a meeting for such time and place as shall be designated by them in writing Members must receive at least two days notice in letter or telegram from the Society's office

Sec. 4 A quorum shall consist of eleven members

Sec. 5 The Council of Trustees shall have charge of all property including trust funds and shall supervise the financial affairs of the Society and shall invest the surplus from time to time, and all resolutions or recommendations of the House of Delegates pertaining to expenditure of money must be approved by the Council of Trustees before the same shall become effective. The administrative year shall begin July 1 and end June 30 of the following year

Sec. 6 All moneys of the Society received by the Council of Trustees or any member or agent thereof shall be paid to the Treasurer of the Society The Council of Trustees shall approve the bond of the Treasurer and the Assistant Treasurer as to amount, form and surety, and shall employ a certified public accountant licensed by the State of New York to audit the accounts of the Treasurer and Secretary and other agents of the Society and present a statement of the same in its Annual Report to the House of Delegates

Sec. 7 The Council of Trustees shall take such action as is necessary to carry out the Constitution and By-Laws and to give full effect to any resolution or vote of the House of Delegates It shall also have power to legislate as a House of Delegates, when the latter is not in session, on all matters consistent with the Constitution and By-Laws

Sec. 8 The Council of Trustees shall have power to fill any vacancy which may occur in any elective office not otherwise provided for, until the next annual meeting of the House of Delegates

Sec. 9 The Council of Trustees shall have responsibility for all publications of the Society and their distribution Any Special Committee of the Society shall report to the Council of Trustees and shall be subject in all ways to the Council of Trustees unless otherwise instructed by the House of Delegates The Council of Trustees shall advise the legal counsel in actions brought against members for alleged malpractice With the aid of legal counsel, it shall examine the Constitution and By-Laws of component County Societies and District Branches and all amendments thereto which may be submitted to the Council of Trustees for approval and shall approve or disapprove of said amendments

Sec. 10 No Board, Commission, or Committee shall inaugurate or initiate any policy or commit the Society to any policy unless the same has been expressly approved by the House of Delegates or by the Council of Trustees

Sec. 11 The duties of the Council of Trustees shall also include the study and/or supervision of the following activities

- (a) All Scientific Work presented at each annual meeting
- (b) Scientific Exhibits
- (c) Medical Education
- (d) Journal Management and Publication.
- (e) Medical and related research
- (f) Arrangements for annual meeting
- (g) Preventive Medicine
- (h) Public Health
- (i) Legislation
- (j) Economics
- (k) Workmen's Compensation
- (l) Health and Welfare Departments of State
- (m) Medical Publicity
- (n) Hospitals, Clinics, and Welfare Agencies
- (o) Cooperative Relationships with Federal and State Governments, Foundations and other lay groups
- (p) Malpractice Defense and Insurance.

Sec. 12 Subcommittees of the Council of Trustees may include other members of the Society and may be nominated by the President subject to the approval of the Council of Trustees Each subcommittee shall include at least one member of the Council of Trustees who shall be chairman, except that he need not be chairman for subcommittee or subcommittees in charge of

- 14 Unfinished Business
- 15 New Business
- 16 Adjournment.

Chapter III

Election of Officers, Trustees and Delegates

Sec 1 The Officers and the Trustees of the Society and the Delegates to the American Medical Association shall be elected at the last adjourned session of the annual meeting of the House of Delegates, which adjourned session shall be held at a convenient hour on the first, second, or third day of the annual meeting of the Society. No member of the Society who is in arrears for County dues or State Society per capita assessment shall be eligible for any office or entitled to vote for any officer, trustee or delegate.

Sec 2 The President, the President-Elect, who shall serve as first Vice-President, the second Vice-President, the Treasurer, the Assistant Treasurer, the Speaker and the Vice-Speaker of the House of Delegates shall be elected for one year or until their successors have been duly chosen.

Three other members of the Council of Trustees shall be elected annually for a term of five years, except in 1937, when three members shall be elected for five years, three for four years, three for three years, three for two years and three for one year. In the event of a vacancy, a Trustee shall be elected for the unexpired term.

Sec. 3 The first order of business at the last adjourned session of the House of Delegates of each annual meeting shall be the nominations for officers of the Society and other members of the Council of Trustees and delegates to the American Medical Association and the appointment of a sufficient number of tellers by the Speaker. After all nominations shall have been made the Secretary shall cause to be displayed in full sight of the delegates a list of nominees for each office arranged in alphabetical order, and shall also cause to be distributed a sufficient number of blank ballots for the use of the House of Delegates. These ballots shall have printed or stamped thereon the appropriate headings for each office with spaces thereunder in which may be written the name of the candidate or candidates to be voted for.

Sec 4 All elections for such offices and

positions shall be by ballot, each member depositing his ballot on roll call individually. In the event of a single nominee only for any office or position, a majority vote without ballot shall elect. In case no nominee for an office receives a majority of votes on the first ballot, the nominee receiving the lowest number of votes shall be dropped and a new ballot taken for that office. This procedure shall be continued until one of the nominees receives a majority of the votes cast when he shall be declared elected.

Sec. 5 The following method shall govern the election of delegates to the American Medical Association. Nominations shall be made for not less than double the full number of delegates to be elected, and the delegates shall be declared elected in the order of the highest number of votes cast until the allotted number shall have been chosen, a corresponding number in the next highest order of votes cast shall be declared alternate delegates. When the full number of delegates are not available for attendance at the meeting, the President shall appoint and certify a sufficient number to complete the quota.

Sec. 6 The delegates to the American Medical Association shall be elected in the calendar year preceding the meeting of the House of Delegates of the American Medical Association, to which they are elected and in accordance with the Constitution and By-Laws of that body for a term of two years. Delegates may be elected to other medical societies or similar bodies as the interests of the Society may require, and credentials shall be issued to all delegates, signed by the President and Secretary.

Chapter IV

Council of Trustees

Sec 1 The Council of Trustees shall be the Executive and Administrative body of the Society while the House of Delegates is not in session and shall control all arrangements for the annual meeting. It shall prepare an annual budget. Its resolutions and actions shall be decisive and final except that all resolutions and actions of the Council of Trustees are subject to review, reconsideration, and action by the House of Delegates. Its actions shall be governed by the Constitution and By-Laws of the Society and the rules and regulations of the House

or reverse by a two-thirds vote of the Censors present and voting, the decisions so appealed from. If, in its opinion, the taking of further evidence is advisable, the Board of Censors may summon witnesses and proceed to take such evidence in such manner as it may deem proper and render its decision by a two-thirds vote of those present and voting, which decision shall be binding until reversed or modified by the House of Delegates.

Sec. 7 The Board of Censors shall investigate all charges preferred (a) by a member of a component County Society against any component County Medical Society of which he is not a member, and (b) by a component County Medical Society against another such County Society or a member thereof, and the Secretary of the Board of Censors shall submit the report to the House of Delegates for action thereon.

Sec. 8 A party desiring to appeal to the House of Delegates from the decision of the Board of Censors shall within three months after such decision, file with the Secretary of this Society and the Secretary of the component Society a notice of appeal. Such notice of appeal shall set forth in writing the name of the appellant, the name of the component County Society, the date and substance of the decision appealed from and the ground or grounds upon which such appeal is taken. The appellant must also state if he desires to be present in person or by counsel.

Sec. 9 Upon the filing of a notice of appeal the appellant and the Secretary of the Board of Censors shall submit to the House of Delegates the decision and all records, minutes, letters, papers, and all written evidence including a digest of all testimony not stenographically reported relating to the matter.

Sec. 10 The House of Delegates shall consider and decide the appeal on the data submitted to it, and may affirm, modify or reverse the decision so appealed from. Such decision of the House of Delegates shall be final and binding.

Chapter VI

Duties of Officers

Sec. 1 The President shall preside at all meetings of the Society, the Council of Trustees, and the Censors. He shall be ex-officio member of the Board of Censors and

of all committees. He shall appoint all committees not otherwise provided for, subject to the approval of the Council of Trustees. He shall assign the special branches of work for which the members of the Council of Trustees shall be responsible, subject to the approval of the Council of Trustees. He shall also appoint all members of sub-committees of this Council subject to the approval of the Council of Trustees. The President shall deliver an address at the annual meeting of the Society. He shall perform such other duties as the House of Delegates or the Council of Trustees shall require.

Sec. 2 The President-Elect shall perform the duties of the President in the absence of the President. In the event of the President's death, resignation, removal, incapacity or refusal to act, the President-Elect shall succeed him.

Sec. 3 The immediate past President shall be a member of the Council of Trustees.

Sec. 4 The Speaker shall preside at all meetings of the House of Delegates. He shall appoint all parliamentary committees to serve during the meeting of the House of Delegates at least thirty days in advance of the meeting. All resolutions submitted by County Medical Societies and District Branches to be presented to the House of Delegates should be forwarded to the Speaker at least forty-five days in advance of the annual meeting of the House and referred by him to the appropriate Reference Committee.

Sec. 5 The Vice-Speaker shall perform the duties of the Speaker when requested by the Speaker to do so, or in case of the absence, death, resignation or refusal of the Speaker to act.

Sec. 6 The Secretary shall attend all meetings of the Society, the House of Delegates, the Council of Trustees, and the Board of Censors, and shall keep minutes of their respective proceedings. These minutes shall be copied from a stenographer's notes with such deletion only as will not modify, alter, or becloud the history of the actions of the said bodies. The stenographer's typewritten copy shall be preserved until ordered destroyed by the Council of Trustees.

The Secretary shall be responsible for and have general charge of the Society's offices and the employees therein. He shall be the custodian of the seal of the Society, and of all books of records and papers belonging to the Society, except such as prop-

activities "A", "B" and "F", Chapter IV, Section 11 of the By-Laws. The Membership of subcommittees shall not exceed three, including the chairman except subcommittee or subcommittees in charge of activities "A", "B" and "F". Chapter IV, Section 11 of the By-Laws.

Sec. 13 The following shall be the order of business at meetings of the Council of Trustees

- 1 Calling the meeting to order
- 2 Roll Call
- 3 Reading of Minutes
- 4 Communications
- 5 Report of the Secretary
- 6 Report of Treasurer
- 7 Report of Committees
- 8 Unfinished Business
- 9 New Business
- 10 Adjournment.

CHAPTER V

Board of Censors

Sec. 1 Members of the Board of Censors shall be nominated each year by the President and approved by the Council of Trustees at its first meeting following the annual meeting of the House of Delegates. They shall hold office for one year or until their successors are elected. The President of the Society shall sit as the presiding officer of the Board of Censors but shall vote only in case of a tie. The Secretary shall sit as Secretary of the Board without vote. The Board of Censors shall meet upon the call of the President. It shall report its findings to the House of Delegates.

Three Censors (not including the President) shall constitute a quorum. Each District Branch shall be represented upon the Board of Censors one year in each two years. When an appeal involves a member or members or a County Society or Societies in the jurisdiction of a Censor such Censor shall be disqualified to act as a member of the Board of Censors and the President shall nominate an alternate for him in the person of another District Branch President who is not regularly serving as Censor.

When an appeal involves a member or members or a County Society or Societies within the District in which the President resides, he shall be disqualified to act as a member of the Board of Censors and the First Vice-President shall serve in his stead.

Sec. 2 The Board of Censors shall have jurisdiction to hear and determine all appeals from decisions on discipline of component County Medical Societies or decisions of such Societies which may involve the privileges, rights or standing of members whether in relation to one another or to County Medical Societies or to this Society. Any member of any component County Medical Society feeling aggrieved by the decision of such Society may within three months after such decision appeal to the Board of Censors of this Society from the decision of such component County Medical Society by filing a notice of appeal with the Secretary of this Society, and the Secretary of the component County Society.

Sec. 3 Any applicant for membership in a component County Medical Society who may have been excluded from membership in such Society, may likewise appeal from the action of said Society excluding him. All decisions shall be subject to appeal to the House of Delegates.

Sec. 4 The notice of appeal shall set forth in writing the name of the appellant, the name of such component County Medical Society and the date and substance of the decision appealed from and shall indicate the ground or grounds upon which such appeal is taken. If the appellant desires to be present in person or by counsel at the hearing of said appeal, the notice of appeal must so state. In that event, the appellant must file with the notice of appeal a bond in the sum of \$500 to cover the costs of said appeal. If the appellant fails to appear in person or by counsel upon the hearing of said appeal he shall forfeit to the Medical Society of the State of New York such share of said bond as represents necessary expenditures incident to convening the Board of Censors for the hearing of said appeal.

Sec. 5 Upon filing a notice of appeal, the appellant and the component County Medical Society shall submit to the Secretary of the Board of Censors all records, minutes, letters, papers, and all written evidence including a digest of all testimony not stenographically reported relating to the matter. All data so submitted shall be available only to the Censors, and on appeal, to the members of the House of Delegates.

Sec. 6 The Board of Censors shall consider the appeal on the data so submitted to it, and may affirm by a majority vote, modify

or reverse by a two-thirds vote of the Censors present and voting, the decisions so appealed from. If, in its opinion, the taking of further evidence is advisable, the Board of Censors may summon witnesses and proceed to take such evidence in such manner as it may deem proper and render its decision by a two-thirds vote of those present and voting, which decision shall be binding until reversed or modified by the House of Delegates.

Sec. 7 The Board of Censors shall investigate all charges preferred (a) by a member of a component County Society against any component County Medical Society of which he is not a member, and (b) by a component County Medical Society against another such County Society or a member thereof, and the Secretary of the Board of Censors shall submit the report to the House of Delegates for action thereon.

Sec. 8 A party desiring to appeal to the House of Delegates from the decision of the Board of Censors shall within three months after such decision, file with the Secretary of this Society and the Secretary of the component Society a notice of appeal. Such notice of appeal shall set forth in writing the name of the appellant, the name of the component County Society, the date and substance of the decision appealed from and the ground or grounds upon which such appeal is taken. The appellant must also state if he desires to be present in person or by counsel.

Sec. 9 Upon the filing of a notice of appeal the appellant and the Secretary of the Board of Censors shall submit to the House of Delegates the decision and all records, minutes, letters, papers, and all written evidence including a digest of all testimony not stenographically reported relating to the matter.

Sec. 10 The House of Delegates shall consider and decide the appeal on the data submitted to it, and may affirm, modify or reverse the decision so appealed from. Such decision of the House of Delegates shall be final and binding.

Chapter VI

Duties of Officers

Sec. 1 The President shall preside at all meetings of the Society, the Council of Trustees, and the Censors. He shall be ex-officio member of the Board of Censors and

of all committees. He shall appoint all committees not otherwise provided for, subject to the approval of the Council of Trustees. He shall assign the special branches of work for which the members of the Council of Trustees shall be responsible, subject to the approval of the Council of Trustees. He shall also appoint all members of sub-committees of this Council, subject to the approval of the Council of Trustees. The President shall deliver an address at the annual meeting of the Society. He shall perform such other duties as the House of Delegates or the Council of Trustees shall require.

Sec. 2 The President-Elect shall perform the duties of the President in the absence of the President. In the event of the President's death, resignation, removal, incapacity or refusal to act the President-Elect shall succeed him.

Sec. 3 The immediate past President shall be a member of the Council of Trustees.

Sec. 4 The Speaker shall preside at all meetings of the House of Delegates. He shall appoint all parliamentary committees to serve during the meeting of the House of Delegates at least thirty days in advance of the meeting. All resolutions submitted by County Medical Societies and District Branches to be presented to the House of Delegates should be forwarded to the Speaker at least forty-five days in advance of the annual meeting of the House and referred by him to the appropriate Reference Committee.

Sec. 5 The Vice-Speaker shall perform the duties of the Speaker when requested by the Speaker to do so, or in case of the absence, death, resignation or refusal of the Speaker to act.

Sec. 6 The Secretary shall attend all meetings of the Society, the House of Delegates, the Council of Trustees, and the Board of Censors, and shall keep minutes of their respective proceedings. These minutes shall be copied from a stenographer's notes with such deletion only as will not modify, alter, or becloud the history of the actions of the said bodies. The stenographer's typewritten copy shall be preserved until ordered destroyed by the Council of Trustees.

The Secretary shall be responsible for and have general charge of the Society's offices and the employees therein. He shall be the custodian of the seal of the Society, and of all books of records and papers belonging to the Society, except such as prop-

erly belong to the Treasurer, and shall keep an account of and promptly turn over to the Treasurer all funds of the Society which come into his hands. He shall provide for the registration of the members at all sessions of the Society. With the aid and cooperation of the Secretaries of the County Societies, he shall keep a proper register of all the registered physicians of the State by counties. He shall aid the officers of the District Branches in the organization and improvement of the County Societies and the extension of the power and influence of the Society. He shall conduct the official correspondence, notifying members of meetings, Officers, Trustees and Board members of their election and committees of their appointment and duties. He shall affix the seal of the Society to all credentials issued to members of the Society elected by the House of Delegates and to such other papers and documents as may require the same. He shall make an annual report to the House of Delegates. He shall supply each County Society with the necessary blanks for making their annual reports to this Society. Acting in cooperation with the Council of Trustees, he shall prepare and issue all programs. He shall be ex-officio a member of all boards and committees, without vote. He shall record the name and date of admission of each member of the Society.

Sec. 8 The Assistant Secretary shall aid the Secretary in the work of his office and in the absence or disability of the latter, he shall perform the duties of the office until the Secretary resumes the work, or in case of a vacancy until a successor shall be elected.

Sec. 9 The Treasurer shall keep accurate books of accounts of all moneys of the Society which he may receive, and shall disburse the same when duly authorized, but all checks drawn by the Treasurer upon the funds of the Society shall be countersigned by the Secretary of the Society. He shall collect, on or before the first day of June in each year, from the Treasurer of each component County Society the State per capita assessment. He shall at the expense of the Society give a bond for the faithful performance of his duties, which shall be approved by the Council of Trustees as to amount, form, and surety. He shall make an annual report to the House of Delegates and monthly reports to the Council of Trustees. He shall be a member of the Council of Trustees.

Sec. 10 The Assistant Treasurer shall aid the Treasurer in the work of his office, and in the absence or disability of the latter, he shall perform the duties of the office until the Treasurer resumes the work, or in case of a vacancy until a successor shall be elected. He shall, at the expense of the Society, give a bond for the faithful performance of his duties, which shall be approved by the Council of Trustees as to the amount, form, and surety. He shall be entitled to all the rights and privileges of the office while acting as Treasurer.

Sec. 11 Concerning substitutions in office.

The Second Vice-President, the Assistant Secretary, the Assistant Treasurer and the Vice-Speaker shall serve as the First Vice-President, the Secretary, the Treasurer and the Speaker, respectively, whenever these senior officers are incapacitated for service by injury, ill health of themselves or families, imperative professional duties, or by other mandatory absences. This shall be construed so as to include duty at or during meetings of the Council of Trustees, as well as the other official duties designated for the senior officer. The senior officer shall promptly notify the junior officer of his incapacity and request his attention to said duties.

Sec. 12 Each President of a District Branch shall visit the County Societies of his district at least once a year and make a careful inquiry of the condition of the profession in each county in his district and shall report thereon to the House of Delegates.

Chapter VII

Direction of Activities

Sec. 1 (a) An officer to be known as the Director of Activities shall be employed by the Society. He shall be a member of the Medical Society of the State of New York, who has established a reputation for executive ability, and who will give his full time and undivided attention to the affairs of the Society. He shall have been in actual practice for at least ten years or shall have qualifications which in the opinion of the Council of Trustees are equivalent to the same.

(b) The duties of the Director of Activities shall be as follows. He shall have general management of the executive details of the Society's business, subject to the Council of Trustees, he shall be the coordinator of

all activities of the Society, he shall act as Secretary of the House of Delegates, of the Council of Trustees, and of the Board of Censors. Upon the signing of his contract with the Society, he shall automatically become the Secretary of the Society and assume all duties designated for the Secretary in Chapter VI, Section 6.

Sec 2 An officer to be known as the Associate Director shall be employed by the Society. He shall assist the Director of Activities. He shall be a member of the Medical Society of the State of New York, who has established a reputation for executive ability and who will give his full time and undivided attention to the affairs of the Society, subject to the direction of the Council of Trustees and the Director of Activities. He shall have been in actual practice at least seven years, or shall have qualifications which in the opinion of the Council of Trustees are equivalent to the same. Upon the signing of his contract with the Society, he shall automatically become the Assistant Secretary of the Society.

Sec. 3 The terms of service of the Director of Activities and the Associate Director shall correspond with the administrative year of the Society, i.e. July 1 of one year to June 30 of the following year.

Chapter VIII

Meetings

Sec. 1 The notices of the annual and special meetings of the Medical Society of the State of New York, and its House of Delegates, and of regular meetings of the Council of Trustees, and the Board of Censors, shall state the date, place and hour and shall be mailed in securely post-paid wrapper to each member of the body holding such meeting at least seven days before said meeting. The affidavit of mailing by the Secretary of the Society to the last recorded address of the member shall be deemed sufficient proof of the service upon each and every member for any and all purposes.

Sec. 2 Each member in attendance at the annual or special meeting of the Society shall enter his name and the name of the component County Medical Society to which he belongs in a register to be kept by the Secretary of the Society for that purpose. No member shall take part in any of the

proceedings of such a meeting until he shall have complied therewith.

Sec 3 All members in good standing so registered may attend and participate in the proceedings and discussions of the general meetings of the Society and of the Sections.

Sec. 4 The following shall be the order of business at all general meetings of the Society:

- 1 Calling the Society to order
- 2 Address of welcome by the Chairman of the Committee on Arrangements
- 3 Reading the minutes of the last meeting
- 4 Miscellaneous business
- 5 President's address
- 6 Special addresses
- 7 Reading and discussion of papers

Sec 5 Special meetings of the Society shall be called by the President upon the request in writing of two hundred and fifty members from the membership of at least ten component County Societies, and in case of the failure, inability or refusal of the President to act, such meeting may be called by a notice thereof subscribed by two hundred and fifty members.

Sec. 6 Special meetings of the House of Delegates shall be called by the Speaker upon the request in writing of sixty delegates, or at request of the Council of Trustees, and in case of the failure, inability or refusal of the Speaker to act, such meetings may be called by a notice thereof subscribed by sixty delegates.

Chapter IX

Expenses

Sec 1 Allowances for expenses incurred in the actual performance of official duties by officers, members of the Council of Trustees, Board of Censors, and committees, and delegates to the American Medical Association shall be made in conformity with the following conditions. The President shall be allowed a *per diem* and expenses when engaged upon official business. All other officers shall be allowed travelling expenses when engaged upon official business. Members of the Council of Trustees, Board of Censors, shall be allowed travelling expenses. Members of committees and subcommittees of the Council of Trustees, Board of Censors, shall be allowed travelling expenses. Proper vouchers must be filed with the Secretary and approved by the Council of Trustees before any of above allowances are made. The delegates to the

American Medical Association who have attended each session of the House of Delegates of that Association and who shall have filed with the Secretary evidence of such attendance shall be allowed the actual cost of railroad transportation and Pullman accommodations to the place of meeting and return. The vouchers of such expense shall be approved by the Council of Trustees before payment. Each District Branch shall be entitled to receive a sum not to exceed \$200 00, exclusive of the work done by the Secretary regarding notices, programs, etc to defray the expenses of holding the annual meeting of such District Branch, provided a proper statement of such expense shall have been presented to the Secretary and approved by the Council of Trustees. All bills, claims or vouchers herein provided for shall be filed within thirty days after the date of the incurring of such expense. This time may be extended for any cause by the Council of Trustees and such extension shall not exceed ninety days.

Chapter X

Reference Committees

Sec 1 At least one month before the meeting of the House of Delegates the Speaker shall appoint and publish in the Journal such Reference Committees as he shall deem expedient for the purposes of the meeting. Immediately after the organization of the House of Delegates he shall formally announce the appointments of the Committees. Only members of the House of Delegates are eligible for appointment on the Reference Committees. Such Committees shall consist of five members, three members constituting a quorum, and shall serve during the meeting for which they are appointed.

Sec 2 Reports of Officers, Council of Trustees, and Committees shall be printed at least one month before the meeting of the House of Delegates and sent to the members of the Reference Committee appointed according to Section 1, for their preliminary consideration. All recommendations, resolutions, measures, and propositions presented to the House of Delegates and which have been duly seconded shall be referred by the Speaker to the appropriate Reference Committees.

Sec 3 Each Reference Committee shall

immediately consider such business as may have been referred to it and shall report promptly to the House.

Chapter XI

Special Committees

Sec 1 Special Committees may be created by the House of Delegates to perform the special functions for which they are created. They shall be appointed by the officer presiding over the meeting at which the committee is authorized, if such committee is to conclude its work during said meeting of the House of Delegates. The President shall appoint all other committees subject to the approval of the Council of Trustees unless otherwise ordered by the House of Delegates.

Sec 2 A Special Committee on Prize Essays consisting of three members, including the Chairman, shall be appointed by the President with the approval of the Council of Trustees. Its duty shall be to receive all essays offered in competition for prizes which may be offered by this Society. The Committee shall make all necessary rules and regulations for the award of prizes subject to the terms of the deeds of gift, and shall report the result at the next annual meeting of the House of Delegates. It shall give notice through the Society's publication or by other methods within thirty days after appointment, of the amount of the prize and when the essays shall be submitted to the Committee.

Sec 3 Any member of the Society shall be eligible to serve on Special Committees. All members of such committees, who are not members of the House of Delegates, shall have the right to present their reports in person to the House of Delegates and to participate in the debate thereon, but shall not have the right to vote.

Sec 4 Completion of Work. In all cases where certain work is being performed or problems studied by any Special Committee, such work or study shall not be considered finished when the tenure of office of such Committee ends, but shall be continued by the succeeding Committee.

Chapter XII

Sections

Sec 1 The Scientific Sections designated by the House of Delegates shall each organ-

ize by the election of a Chairman and Secretary. The Chairman shall be elected annually, the Secretary for such term as the Section may deem fit.

Sec. 2 The officers of the various Sections shall prepare programs for their Sections under the direction and subject to the approval of the Council of Trustees.

Sec. 3 The election of officers of Sections shall be the first order of business of the first session of the second day of each annual meeting. To participate in the election of any Section, a member must be registered with such Section and must have recorded his name and address in the Section registry.

Sec. 4 Each Section shall hold its meetings at such times as designated by the Council of Trustees.

Chapter XIII

District Branches

Sec. 1 Each District Branch shall elect a President for two years, who shall be a District Delegate of the House of Delegates during his term in said office.

Sec. 2 Each District Branch shall elect such officers as are provided for in its By-Laws, who shall attend the business meetings of the Branch.

Chapter XIV

Component County Medical Societies

Sec. 1 Whenever an active member in good standing in any component County Medical Society removes to another County in this State, his name, upon his request, shall be transferred to the roster of the component County Medical Society of the County to which he removes, without cost to him, provided that he files a certificate with the Secretary signed by the President and Secretary of the component Society from which he removes as to his good standing in such Society. No member, however, shall be an active member of more than one component County Society, nor shall any component County Society accept a physician residing in another County in any other way than in accordance with the law governing transfers.

When a member in good standing ceases to reside and practice in the State of New York he shall *ipso facto* cease to be a member of the Society and of his component County Medical Society. His status shall be deemed that of a resigned member and all rights and title to any share in the privileges and property of the Society, the District Branch, or County Society, shall be deemed to have been forfeited by such action.

The dues of any member of the Medical Society of the State of New York may be remitted for the current year on account of illness when the request is made by the member's component County Medical Society.

Sec. 2 At its annual meeting each component County Medical Society shall elect a delegate or delegates to represent it in the House of Delegates of this Society in accordance with the Constitution and By-Laws of this Society.

Sec. 3 The Secretary of each component County Medical Society shall keep a roster of its members in which shall appear the full name of each of said physicians, the date of his admission to such society, his residence, and the date when his license to practice medicine in this State was granted. He shall note any changes in said roster by reason of removal, death or change of name, revocation of license or other disqualification.

He shall forward said roster and information, together with the names and places of residence of each of the officers of said society and the names and residence of each delegate of the House of Delegates of said society to the Secretary of this Society sixty days before the date of its annual meeting.

Sec. 4 The Treasurer of each component County Medical Society shall forward to the Treasurer of this Society the amount of the State per capita assessment on or before the first day of June of each year.

Sec. 5 Each component County Medical Society shall adopt a Constitution and By-Laws for the regulation of its affairs and may amend the same provided they shall be first approved by the Council of Trustees before becoming effective. The Constitution and By-Laws of component County Societies must not be in conflict with the Constitution and By-Laws of this Society.

Chapter XV

Miscellaneous

Sec 1 No address or paper before the Society, except those of the President and orators, shall occupy more than twenty minutes in its delivery, and no member shall speak upon any question before the House of Delegates for longer than five minutes nor more than once on any subject, except by the consent of a majority vote

Sec 2 All papers read before the Society by its members shall become the property of the Society. Permission may be given, however, by the Council of Trustees or House of Delegates to publish such paper in advance of its appearance in the *NEW YORK STATE JOURNAL OF MEDICINE*.

Sec 3 Any distinguished physician of a foreign country or a physician not a resident of this State, who is a member of his own State Association, may become a guest during any annual session upon the invitation of the President or officers of the Society, and may be accorded the privilege of participating in all the scientific work of the session

Sec 4 The rules contained in Robert's Rules of Order shall govern the Society and the House of Delegates in all cases in which they are not inconsistent or in conflict with the Constitution and By-Laws of the Society or the standing or special rules of the House of Delegates

Sec 5 Written charges may be preferred against any officers, Trustees, and members of Boards and Special Committees of the Society, for malfeasance or nonfeasance in office, by any member and transmitted to the President. The President shall order a trial upon said charges by the Council of Trustees or a Committee thereof, and in the event of such trial the accused shall be given at least ten days' notice of such charges and have full opportunity to defend the same, but no such officer or member of the committee

shall be removed or otherwise disciplined except by a two-thirds vote of the Council of Trustees. In case any such officer, or trustee, or member of a board or committee shall be removed, he may appeal from the decision of the said Council of Trustees to the House of Delegates, but pending the determination of such appeal, he shall not exercise the functions of his office.

Sec 6 Sections of the By-Laws which refer to the order of business and to reference committees may be suspended by a two-thirds vote of the House of Delegates

Chapter XVI

Sec 1 The seal of the Society shall be as follows

Chapter XVII

Amendments

Sec 1 Amendments to these By-Laws, except such as are obligatory by law, shall be made only at an annual meeting of the House of Delegates

Sec 2 Notice of the proposed amendment shall be given at a previous annual meeting of the House of Delegates, and before the same can be acted upon it shall be published once before the annual meeting in the official bulletin or journal of the Society

Sec 3 The affirmative vote of two-thirds of the House of Delegates present and voting shall be necessary for adoption

Sec 4 Amendments made necessary by law shall be made either by the Council of Trustees or House of Delegates whenever such necessity exists

O W H MITCHELL, *Chairman, Syracuse*
WALTER W MOTT, *White Plains*
CHARLES H GOODRICH, *Brooklyn*
THOMAS H CUNNINGHAM, *Glens Falls*
JOSEPH C O'GORMAN, *Buffalo*

GEORGE WASHINGTON SCHOOL OF MEDICINE

The Fifth Annual Post Graduate Clinic of the George Washington School of Medicine at Washington, D C., is to be held Saturday, February 20. Clinics will be held, papers will be presented, laboratories will be

open for inspection, and luncheon will be served, all at the Medical School and Hospital. The Banquet of the George Washington Medical Society will be held the same evening at the Mayflower Hotel

REFERENDUM VOTE

Of The 1936 House of Delegates

On December 14, 1936 the Council of the Medical Society of the State of New York ordered a vote by mail which is explained in the following

Memorandum to Members of 1936 House of Delegates

EVENTS AND INFORMATION considered by the Council in deciding that it would be unwise to attempt in 1937 to effect legislation looking toward limitation of "administration of anesthesia to duly licensed physicians and dentists, except in cases of emergency"

I The mandate of the 1936 House was duly passed to the Committee on Legislation, and that Committee has been prepared to act in accordance—unless instructed to the contrary

II The Legislative Committee has at times since April 27, 1936 reported to the Executive Committee and finally to the Council certain facts of which it had been earlier aware and which it later learned. It has found that there is much opposition to the passage of a law at this time because of these facts. It has drawn up a memorandum which accurately states the present status of the matter in the following words

"In anticipating legislation on this subject, the Committee has encountered certain important facts which are of special interest at this time. This matter was sponsored under the so-called 'Crawford Bill' and failed of enactment two years ago. There are on file in the Legislative Bureau letters of protest from some of the most representative members of the State Society vigorously opposing legislation of this nature. We also have protests unanimously adopted by the attending staff of representative hospitals throughout the State opposing this legislation

"The Committee has also interviewed many physicians at random throughout the State and finds that there is a general conflict of opinion as to the wisdom of this proposed legislation at this time. The Legislative Committee undertook to consult with many leading anesthetists of this State, who are members of the State Society, and who represent recognized state and national organizations on anesthesia, and found them to be of the unanimous opinion that this is not an opportune time to seek such legislation. These specialists in anesthesia asked that action be postponed for several reasons. First, that there is not now a sufficient number of medical men willing to take up anes-

thesia to take over the entire work, second, that there are still many prominent physicians, surgeons, and hospitals which prefer nurse anesthetists (of whom there are now about 700 in the State), and if given time they feel that they can remove a great portion of this opposition. We have a letter from the Chairman of the new Session on Anesthesia of the State Society, advising that action be postponed

"From a practical standpoint we must conclude that the profession itself is divided as to the wisdom of this proposed legislation at this time. In this connection we can also anticipate the vigorous and sustained objections of certain hospital and nursing groups. Such militant and widespread opposition has a way of crystallizing itself in legislative halls, and with these hazards already facing such a bill, only the most visionary optimist could hope for its enactment into law at this time

"The legislative Committee is in entire accord with the principle that anesthesia should be developed as a special branch of medicine. We believe that true progress in this field can come only through original observation and research by medical men. From a scientific standpoint we believe that progress is being retarded because this field has been taken over by others. We recommend that the State Society through all its agencies—educational, scientific, and publicity—stress the scientific phase of the practice of anesthesia, encourage and sponsor facilities through which physicians can equip themselves to assume the growing responsibilities which the administration of not only the older, but the newer anesthetics imposes upon us. This done effectively, the proposed legislation will then stand a better chance of enactment."

III On December 10, 1936 there appeared before the Council Dr. T. Drysdale Buchanan representing the New York members of the American Society of Anesthetists, and Dr. Paul Wood of the American Society of Regional Anesthesia. These gentlemen counselled postponement of action for this year, at least—if not longer. Both were strongly in favor of limitation of anesthesia to physicians only, but both were of the opinion that no legislation to that effect should be supported this year, or

until a sufficient time has passed to allow for training of sufficient physicians to replace the large number (700) of nurses now regularly giving anesthesia in the State

IV With this gradually increasing information, culminating in the counsel of the anesthesiologists themselves, the Council, although in full sympathy with the idea of eventual limitation of anesthesia to physicians and dentists only, found itself wholly in favor of delay in pressing for legislation. It, therefore, took the action for 1937 indicated in its formal rescinding resolution

FLOYD S WINSLOW, *President*
PETER IRVING, *Secretary*

January 11, 1937

The following ballot was sent to the 196 members

Referendum Ballot

To Member of 1936 House of Delegates

From The Secretary of the Medical Society of the State of New York.

As directed in Chapter IV, Section 5 of the By-Laws, a question is submitted below which requires your vote as a member of the 1936 House of Delegates

The By-Laws state that the Council "shall also have power to legislate as a House of Delegates, when the latter is not in session, on all matters consistent with the Constitution and By-Laws. Such legislative action of the Council shall not become effective or binding on the Society until approved by a majority of a referendum vote of the House of Delegates, provided a majority of the House of Delegates vote thereon within fifteen days after the mailing of the question submitted for referendum. The Secretary shall send the question for referendum vote to all the members of the House of Delegates."

On April 27, 1936 the House of Delegates recorded a mandate "That the proper com-

mittee of the Medical Society of the State of New York be directed to draft and promote at the 1937 session of the New York State Legislature a bill to limit the administration of anesthesia to duly licensed physicians and dentists except in cases of emergency"

On December 10, 1936 the Council rescinded this mandate by the following resolution "That the action of the 1936 House of Delegates which gave the mandate to the Committee on Legislation to support a bill limiting the giving of anesthesia to physicians be rescinded—this action to be submitted (as provided in the Constitution and By-Laws) to a referendum vote of the 1936 House of Delegates, and that as an aid to voting, a circular be formulated and distributed to the members, which shall set forth the reasons why the Anesthesia Societies advise delay"

The question is SHALL THE ACTION OF THE COUNCIL IN RESCINDING THE ABOVE MANDATE OF THE HOUSE OF DELEGATES BE APPROVED?

In order to aid you to make a decision as directed by the Council, there is attached a memorandum of the events and information which led the Council to its conclusion to rescind

Please indicate your vote hereon, *sign*, and return at your earliest convenience to me, before January 26, 1937, (when the statutory fifteen days will have passed)

YES

NO

Action of Council approved

FOREIGN CONGRESSES NEXT FALL

As an aid in planning a trip abroad next year, it might be noted that on September 13, 14 and 15, 1937 the International Society of Gastroenterology will hold its Second Congress in Paris, France. The subjects to be discussed are "The Diagnosis of Gastric Carcinoma" and "The Acute and Chronic Occlusions of the Small Intestine." This Congress will be immediately followed by the International Congress on Hepatic Insufficiencies to be held in Vichy (90 miles

from Paris) on September 16, 17 and 18. The United States National Committee of the International Society of Gastroenterology has been formed by representatives of the various gastroenterological societies in this country. The allotment of members in the United States is rapidly being filled and those who are interested in any of the phases of gastroenterological work and would like to join, apply to the President, Dr. Anthony Bassler, New York City.

PNEUMONIA CONTROL PROGRAM

Prize for Report on Cases of Pneumonia

The Advisory Committee on Pneumonia Control of the New York State Department of Health offers a prize of one hundred dollars for the best report of a series of cases of pneumonia

The competition is open to all physicians residing and practicing in New York State outside of New York City. Interns in hospitals may compete but the report in all cases should include only those cases actually seen and studied by the writer, and should include all cases of pneumonia of all types and forms treated by him either in private practice or in hospitals during the present winter

In awarding the prize less stress will be laid upon the number of cases than upon the objectivity exhibited by the writer in his description of the cases and upon the originality and independence shown in the interpretation of the clinical features. Credit will be given for the extent to which the newer methods of diagnosis and treatment of cases of lobar pneumonia were employed. If the writer desires, the report may be documented by full clinical histories and laboratory reports, but the report itself should not be longer than 5,000 words and be in a form suitable for publication in the NEW YORK STATE JOURNAL OF MEDICINE

Reports should be in the hands of the Committee not later than August 15 and the award will be made October 1

Address further inquiry to

Dr Edward S Rogers,
Director, Bureau of Pneumonia Control,
New York State Department of Health,
Albany, N Y

That the physicians of the State may have concrete examples of different phases of anti pneumococcus serum treatment of pneumococcus pneumonia, there will appear here case reports selected from the large number received by the State Department of Health on the use of anti pneumococcus serum produced and distributed by it

In order that physicians practicing in New York City or those using effective serum from other sources may also be represented, we hope that physicians who may have had particularly significant experiences with serum will submit short reports to the Pneumonia Editor, New York State Journal of Medicine, 33 W 42 Street, New York City—Editor

Case 2

Report from the records of Robert S MacDonald, M D, Plattsburg

"A woman, thirty-two years of age, had a mastoidectomy on November 22. The operation and postoperative course were without event until the end of the first week when the patient developed evidence of acute respiratory infection with a cough productive of clear mucoid sputum. On November 29 there occurred a sharp elevation in temperature to 103.6° F, pulse ninety, and respiration thirty.

'At this time there were no physical signs in the chest excepting occasional rales at the base of the right lung. A presumptive diagnosis of pneumonia was made. Immediate laboratory examination of sputum showed pneumococcus Type I.

"Serum treatment was instituted without delay. There was no history of allergy and the intradermal test for horse serum sensitivity was negative. Accordingly, the first dose of twenty cc (25,000 units) of Type I antipneumococcus serum (New York State Department of Health, was given intravenously, at 7 00 P M, November 29, presumably the day of onset. At 11 30 P M a second dose of forty cc (50,000 units) was given. Within the next few hours there followed a steady drop in temperature to 100. The pulse and respirations also dropped and the patient showed general clinical improvement. Convalescence was uneventful and recovery complete."

Dr MacDonald's case illustrates what might be termed the use of serum in the abortive treatment of pneumonia. It can, perhaps, be argued that the diagnosis was not completely established because of the scarcity of physical signs and the lack of x-ray confirmation. That this might have been merely an acute respiratory infection which would have run such an abortive course without serum treatment can not be denied. However, on the basis of the data submitted alone it can be stated that excellent clinical judgment was used and that the burden of proof would lie with the one who claimed that it was not pneumonia.

To examine the evidence at hand, the sequence—operation upper respiratory symptoms, and sudden fever—must place pneumonia near the top of the list of diagnoses

to be considered. Fever following any operative procedure and especially a mastoidectomy is not, of itself, of great differential value and other possible septic complications would have to be thought of. Nevertheless, the acute respiratory symptoms and especially the rapid rate are, under such circumstances, highly suggestive of pneumonia. Occasional rales at the base of a lung are treacherous and may or may not be of significance. We need more information about them, which presumably Dr MacDonald had. We may assume that they were constant and newly developed. The presumptive diagnosis of pneumonia in this case, however, could probably have been made even with a total absence of physical signs in the chest.

Middle ear infection is not infrequently encountered as a so-called complication of pneumonia, especially in children. Usually the micro-organism causing the two infections is identical. In adults, and possibly in children more frequently than is realized, the relationship is often reversed and the middle ear infection precedes the pneumonia as apparently occurred in this case.

The laboratory report of Type I pneumococcus is most highly significant and in this instance may be taken as strong confirmation of the diagnosis of pneumonia. Its significance lies in the fact that this micro-organism has been shown to be an extremely infrequent inhabitant of the mouth and throat other than in connection with pneumonia due to it. There are normal carriers of Type I pneumococci, principally persons who have had recent intimate contact with a case, but this particular type of pneumococcus has been demonstrated only to occur in approximately half of one per cent of the general population who have not had such contact. Therefore, the mathematical chance of finding a normal carrier of Type I pneumococci, who presents symptoms suggestive of pneumonia, is so slight that this combination would seem to more than justify a positive diagnosis and prompt serum treatment.

With respect to the amount of serum given it is worth pointing out, as illustrated in this case, that in general the earlier serum is administered the less is required to produce and maintain a favorable response.

COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

From the sub-committee on Child Hygiene, of which Dr Edward J Wynkoop of Syracuse is chairman and whose two other members are Dr Leo F Schiff of Plattsburg and Dr Oliver W H Mitchell of Syracuse comes information in the form of a letter from the Commissioner of Health of the State of New York. Dr Edward S Godfrey, Jr. It was in answer to a query from the sub-committee

December 17, 1935

Dr Edward J Wynkoop, Chairman,
Sub-committee on Child Hygiene,
State Medical Society,
501 James St.,
Syracuse, New York.

My dear Dr Wynkoop

I have your letter of the 10th inquiring as to the provisions of the Social Security Act for maternal and child welfare services

The annual amount available to the State of New York is \$173,386 which must be matched dollar for dollar by State funds, expended for the same purpose

These funds are allotted to the State Department of Health as the State Administering Agency, through its Division of Maternity, Infancy and Child Hygiene.

The purposes for which these funds are granted are to enable each state "to extend and improve as far as is practicable under the conditions in such state, services for promoting the health of mothers and children, especially in rural areas and in areas suffering from severe economic distress"

Matching funds may include not only the expenditures of the state for maternal and child welfare services, but those expended by local political sub-divisions for a like purpose if the work carried on is under the general supervision of the state agency, and their program brought into the state plan.

Among the requirements of the Social Security Act, the State, in its plans, must show evidence of seeking the cooperation of medical, nursing, and welfare groups and organizations. In the following synopsis of the main elements of the program it will be seen that the State Department of Health has planned very definitely to recognize the importance of this cooperation in a very realistic way

1 In order to comply with provisions of the Social Security Act requiring cooperation of the above mentioned groups, a State Advisory Council is being formed to assist the Commissioner of Health in carrying out the purposes

of the act in ways to most benefit the mothers and children of the State of New York. This Council will consist of ten members representing organized medical, dental, welfare and nursing groups

2 After consultation with the appropriate officers of the State Medical Society, a special medical committee will be organized to study and recommend to the State Department of Health, suitable measures for dealing with some of our knottiest problems, i.e., prematurity of birth, birth injuries, congenital malformations. We cannot deal intelligently or effectively with the large number of neonatal deaths until more is known of the why and wherefore of these great losses in infancy and the related factors involved in maternity

3 As plans progress, the itinerant consultations for the instruction and examination of expectant mothers and young children, conducted by state physicians will be turned over to local clinicians, as soon as practicable. For this purpose funds have been set aside for the payment of local pediatric, obstetric and dental clinicians acceptable to the county organizations

4 In cooperation with the County Medical Society, who have appointed a suitable committee, a service long desired by practicing physicians is now in operation in a northern county, on a demonstration basis, i.e., nursing assistance to the physician at delivery. This service must be coordinated with a generalized public health nursing program. Ten public health nurses will be engaged in this work, six of whom will be financed by maternal and child welfare Social Security funds

5 Twelve additional public health nurses financed in a similar manner are distributed among the different sanitary districts for county work.

6 In cooperation with the County Medical Society, in each instance, small child hygiene bureaus will be set up in three cities for the purpose of stimulating the development of an organized child hygiene program in them and in other cities by example. The great bulk of births, deaths of mothers and infants, of stillbirths and neonatal deaths, occur in the urban areas of this state. The State Department of Health should be in position to assist cities, as well as counties, in developing their health work.

7 We are not forgetting the dental organizations. A state committee has already been appointed to meet with and advise the State Commissioner of Health in the development of an effective dental hygiene program. A dentist will be added to the division staff to head a bureau

He will be expected to work with the county organizations in an effort to provide for the creation of more dental facilities and opportunities for education in mouth health, especially, for young children.

8 More knowledge of the values of foods, their economic purchase, selection, and preparation is greatly needed by a very large proportion of our population. This need is being only partially met by securing two additional nutritionists making a unit of three whose services are available to local groups for educational work.

9 Surveys and studies pertinent to the problems of maternal and child health will be made from time to time. Local county societies undertaking their own studies may call upon the division for statistical advisory assistance. This is

a new service which we hope will be used.

10 The State plan for 1937 provides for financial participation in the post-graduate courses in obstetrics and pediatrics proposed by the various county medical societies.

These are the main elements of the State Plan.

Other features may be added or some of these changed as work progresses and needs become apparent. Not all parts of a new enterprise come into being simultaneously. Activities that are promising, in terms of lives saved and health protected, must receive added support, those falling outside these criteria will need to be curtailed.

Very truly yours,

EDWARD S. GODFREY, JR.,
Commissioner of Health

Postgraduate Lecture Courses

A course on obstetrics has been scheduled for the Cattaraugus County Medical Society and will be held in the Solarium, Olean General Hospital, Olean, at 3 00 P. M.

There have been given the following lectures

January 31, "Hemorrhagic States of Pregnancy," Dr. F. C. Goldsborough, Buffalo.

February 7, "Toxemias of Pregnancy," Dr. Edward C. Hughes, Syracuse.

February 14, "Complications of Pregnancy: Heart Disease, Tuberculosis, and Diabetes," Dr. Louis A. Siegel, Buffalo.

There will be given on dates noted these further lectures of the course

February 21, "Delivery Room Problem," Dr. Francis R. Irving, Syracuse.

February 28, "Maternal Welfare," Dr. F. J. Schoeneck, Syracuse.

RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company are presenting the second series of dramatized health broadcasts under the title *Your Health*. The theme for 1936-37 differs slightly from the topic in the first series, which was "medical emergencies and how they are met." The new series is built around the central idea that "100,000 American physicians in great cities and tiny villages, who are members of the American Medical Association and of county and state

medical societies, stand ready, day and night, to serve American people in sickness and in health."

The program will go out on the Blue network instead of on the Red network, as originally announced.

The topics are announced monthly in advance in *Hygeia*, the Health Magazine, and three weeks in advance in each issue of the *J. A. M. A.* The time of the broadcast is Tuesday afternoon at 5 o'clock eastern time.

RULES FOR HANDLING A WOMAN BY ELECTRICITY

If she talks too long—Interrupter
If she wants to be an angel—Transformer
If she is picking your pockets—Detector
If she will meet you half way—Receiver
If she gets too excited—Controller
If she gets up in the air—Condenser
If she wants chocolates—Feeder
If she sings inharmoniously—Tuner

If she is out of town—Telegrapher
If she is a poor cook—Discharger
If she is too fat—Reducer
If she is wrong—Rectifier
If she gossips too much—Regulator
If she becomes upset—Reverser

—*The Locomotive*

COMMITTEE ON LEGISLATION

Bulletin No 3

January 28, 1937

The following bills have been introduced since the issuance of our last bulletin

Senate Int. 173—Kleinfeld, Assembly Int 196—McCreery, amends the Civil Practice Act, relative to taking of testimony by deposition Referred to the Codes Committees

Comment We understand that under this bill physicians called as witnesses on compensation or injury cases might submit their testimony as a deposition

Senate Int. 210—Hanley, Assembly Int 262—Wadsworth, amends the Public Welfare Law by providing no person or member of his family becoming member of State Tuberculosis Hospital in Mount Morris, Livingston County, shall gain settlement in county or town until he has resided in county for five consecutive years Referred to the Relief and Welfare Committees

Comment Livingston County asks the same protection as has been granted to a number of other counties where tuberculosis hospitals are located

Senate Int 246—Doyle, Assembly Int 275—Langenbacher, adds new article to the Public Health Law, establishing a division of food in the Health Department to investigate economical methods of preparation, value and standards for foods served for human consumption, to establish codes of fair competition for employers and employees preparing and serving foods, and appropriating \$50,000 Referred to the Finance Committee in the Senate and Ways and Means Committee in the Assembly

Comment A companion to this bill provides for the creation in the Department of Agriculture a division of foods that complements the activities deposited in the Department of Health by this bill The two are covering the provisions that are incorporated in a food bill which is now before Congress

Senate Int 259—Twomey, Assembly Int 302—Bush, Mental Hygiene Law, strikes out the specified divisions in Mental Hygiene Department and authorizes the Commissioner to establish as many divisions as he deems necessary, also to appoint one or more assistant commissioners, each of whom shall be a physician of at least five years' actual experience in institutional care of mental defectives Referred to the Finance Committee in the Senate and the Health Committee in the Assembly

Senate Int 274—McCall, adds new article

to the Tax Law, imposing a stamp tax on tobacco and tobacco products, including cigars and tobacco products generally, and for disposition of moneys from such tax for the establishment and maintenance of free dental clinics for school children Referred to the Taxation Committee

Senate Int. 298—Murray, Assembly Int 423—Neustein, authorizes New York City to establish summer vacation school camps for children in parks adjacent to city and under control of a state council of parks where study courses not exceeding ten hours a week shall be given in camp sanitation, elementary hygiene, first aid to injured, life-saving, swimming, and physical training, and authorizing city to appropriate \$5,000,000 Referred to the New York City Committees

Senate Int. 313—Feld, Assembly Int. 298—Mandel, amends the Education Law by striking out provision exempting first-class cities from requirement for medical inspection of pupils Referred to the Education Committee in the Senate and the Health Committee in the Assembly

Comment The section of the Education Law which provides for the medical inspection of school children exempts cities of the first class In New York City the function has rested with the Department of Health Mr Mandel is of the opinion that the medical examination of children is highly important and would be done more effectively if the entire responsibility rested with the Department of Education This bill simply removes the exemption

Senate Int 316—Feld, Assembly Int 312—McCaffrey, adds new Article 51-a to the Education Law, for licensing clinical laboratory technicians, setting up standards of education, and rules for advisory council and examining board in Department of Registration under the Board of Regents Referred to the Education Committees

Comment You will recall that there have been efforts made in previous years to license technicians, which we have opposed on the ground largely that it is difficult to define a technician This bill on first reading does not seem to have adjusted that difficulty If any of the bulletin readers are particularly interested in reading the printed bill, we shall be glad to send them a copy

Senate Int. 358—Esquirol, repeals Art. 52, adds new Art 52, Education Law, providing for the licensing of registered nurses and nursing aides by board of three or more examiners, and making general rules and regulations in connection therewith Re-

ferred to the General Laws Committee.

Comment This is one of the three bills which we understand are to be introduced this year affecting the licensure of registered nurses. This bill was prepared by the New York State Nurses' Association in conjunction with the Department of Education. It has been reviewed by the Subcommittee on Nursing of our Committee on Public Health and Medical Education. If you are interested and wish to read the bill, we shall be glad to send you a copy.

Assembly Int. 260—Sutor, adds new article to the Vehicle and Traffic Law for care of indigent persons suffering from motor vehicle injuries in hospitals not organized for profit and registered by State Health Department, per diem cost not to exceed \$6.00 a day, and appropriating \$350,000. Referred to the Ways and Means Committee.

Comment Mr Sutor introduced this bill at the close of last year's session, too late for consideration. It is framed along the lines of an Ohio law. Conditions under which hospitals are financed differ so much in the two states that probably this provision can not be applied here. At any rate, we should like to see the provision extended to protect the doctor and nurse as well as the hospital.

Assembly Int. 299—Bush, amends the Public Health Law, prohibiting persons other than licensed physicians, dentists, and veterinarians to possess or cultivate live pathogenic micro-organisms or viruses without permit from the Health Commissioner, and making other changes. Referred to the Health Committee.

Assembly Int. 311—McCaffrey, creates commission to study causes, extent, and prevention of juvenile delinquency, and appropriates \$15,000. Referred to the Ways and Means Committee.

Assembly Int. 327—Jarema, amends the Domestic Relations Law, requiring certificate of physician on applications for marriage license to effect that contracting parties are free from any venereal or communicable disease by an examination had not more than 30 days prior to issuance of license. Referred to the Judiciary Committee.

Comment This bill carries a very broad provision. It not only would prevent the issuance of a license to persons having a venereal disease, but also any other communicable disease, as, for instance, tuberculosis. The provision that the examination may be made as long as thirty days before the time the application for license is filed, weakens the assurance that the applicants are free from the venereal diseases, at least

Assembly Int. 335—McCaffrey, amends the Workmen's Compensation Law relative to physical examination of employees by striking out provision that physician, as employee or carrier may select and pay for, may participate in examination if employee or carrier so requests. Referred to the Labor Committee.

Comment Mr McCaffrey has reintroduced the bill that he has carried for a number of years, which would prevent any other physicians from being present when physicians from the Department of Labor are examining injured employees. The object of the bill is to prevent the carrier's physician from attending the examinations, but in order to accomplish this the presence of the attending physician must also be denied. It has been submitted at legislative hearings, both by physicians and representatives of labor, that it is usually very difficult for the attending physician to be present, while the physician for the insurance carrier is ever present.

Assembly Int. 346—Andrews, amends the Public Health Law by changing designation of Social Hygiene Division to that of Syphilis Control. Referred to the Health Committee.

Comment The Department of Health desires to abandon the title "Social Hygiene" and use a more accurately descriptive term for the Division which will direct the syphilis control campaign which the State has entered into in conjunction with the Federal Government.

Assembly Int. 355—Breitbart, amends the Domestic Relations Law by prohibiting a town or city clerk from accepting application for marriage license unless accompanied by record of standard laboratory blood test. Referred to the Judiciary Committee.

Comment Mr Breitbart specifies that the examination which applicants for a marriage license shall secure from a licensed physician must include a blood test and the physician's opinion that, if infected with syphilis, they do not have it in a communicable stage. He does not require a statement regarding the existence of any other communicable disease.

Assembly Int. 365—Jarema, authorizes New York City to establish summer vacation camps for children in parks adjacent to city and under control of state council of parks, where study courses not exceeding ten hours a week shall be given in camp sanitation, elementary hygiene, first-aid to injured, life-saving, swimming, and physical training, and authorizing city to appropriate \$1,000,000. Referred to the New York City Committee.

Comment This bill differs from Senate Int 298 and Assembly Int 423 only by authorizing an appropriation of \$1,000,000 instead of \$5,000,000

Assembly Int 370—McCaffrey, repeals Art 52, adds new Art 52, Education Law, providing for the license of registered nurses by a board of seven examiners, two to be nominated by State Nurses' Association, requiring registration fee of \$10 00, and making general rules and regulations in connection therewith Referred to the Education Committee

Comment This is one of three bills which we understand are to be introduced this year relating to the licensure of nurses If you are interested in this bill, we shall be glad to send you a copy

Assembly Int. 471—E S Moran, adds new section to the Education Law for issuing permanent injunction against illegal practice of a profession. Referred to the Education Committee

Comment The Attorney General's office tried to prevent a chiropractor from treating sick people by enjoining him on the ground that he was not licensed to do that work, but under our laws at present there was difficulty in securing such an injunction This bill was introduced last year but too near the close of the session to receive proper consideration

Assembly Int 476—Turshen, amends the

Vehicle and Traffic Law, requiring applicant for operator's or chauffeur's license to furnish medical certificate of physical ability to operate motor vehicle, renewal to be withheld unless there is an examination for ear, hearing and general health test at least once in five years, also permitting commissioner to provide space on license for recording convictions Referred to the Motor Vehicles Committee

Assembly Int 485—Brownell, adds new sections 334-a, b, c, Public Health Law, requiring persons employed in places licensed to sell food or drink, to have a food handler's certificate issued annually by State Health Department, or in New York City by City Health Department, to effect that such person is free from a communicable disease Referred to the Health Committee

Assembly Int 503—Fite, adds new section to the General Municipal Law requiring city or town in which parents or mother reside to pay \$75 00 toward expense in child-bearing, payments first to be made to hospital and balance, if any, to be paid to parents for expense, and unexpended balance to city or town for a continuing fund Referred to the Cities Committee.

FRACTURE DAY

"Fracture Day" under the auspices of the New York and Brooklyn Regional Fracture Committee of the American College of Surgeons will be held February 26, 9 30 A M to 4 30 P M, at the New York Academy of Medicine, and will be open to every one interested in fracture treatment

Luncheon can be obtained at a nominal price Kindly notify the Secretary, Herbert M Bergamini M D, 101 East 89 St New York City, before February 20, if you expect to have luncheon at the Academy Partial program follows

'The Committee on Fractures," Dr Frederic W Bancroft
'The Aims and Accomplishments of the Regional Committee" Dr Fenwick Beekman
'Fixed Traction Transportation" Dr Robert H Kennedy
'Occupational Therapy" (motion pictures), Dr Joseph Tenoppy

"The Value of Follow-up Clinics," Dr S Potter Bartley

"Problems in Children," Dr James R Lincoln

"Fracture of the Lateral Condyle of the Humerus in Children" Dr Philip D Wilson

"The Treatment of Radial Head Fractures," Dr Clay Ray Murray

"Unusual Case of Multiple Fractures," Dr Chester L Davidson

"Fracture of Both Astragali Bilateral Astraglectomy," Dr George B Reitz

"A Method of Reduction and Retention in Forearm Fractures," Dr F C Courten

"Compression Fracture of Spine Treated by Automobile Jack Decompression," Dr Otho C Hudson

"Deformity of the Wrist Following Resection of the Radial Head" Dr Raymond W Lewis and Dr A A. Thibodeau

"Fractures and Dislocations of the Cervical Spine," Dr Archie M Baker

"Anesthetic Procedures in the Treatment of Fractures," Dr E. A Rovenstine

Economics

The annual dinner of the Faculty Association of the New York Post-Graduate Medical School and Hospital was held January 23 at the Hotel Biltmore in New York City with some five hundred members of the professional staff and their guests in attendance. Dr Clarence G Bandler, President of the Faculty Association, presided.

Organized medicine was the keynote of the address which followed the dinner and participating in the program were men outstanding for their contributions along this line. The subject is particularly pertinent at the moment, since the Federal Government has so recently intimated that the organized medical profession may be called upon to help solve some of the nation's growing problems of public health and public welfare, and was selected, according to Dr Bandler, with a view to rallying the profession to a realization of the responsibilities and opportunities now before them.

Dr Charles Gordon Heyd, President of the American Medical Association, declared opposition to all compulsory health insurance schemes and gave a statement of the principles that organized medicine will accept and those it will oppose. Following closely upon President Roosevelt's recent message to Congress, in which he recommended the creation of a Department of Public Welfare, this statement had special significance in view of the fact that Dr Heyd, as president of the American Medical Association, is speaking for some 103,000 members of the profession across the country. He said, in part:

The outstanding defect of voluntary or compulsory health insurance is that it divides the practice of medicine into a class practice and the measure of effectiveness of the medical service is dependent upon the economic status of the patient. There is thus created a superior type of medical service for the well-to-do, and a substandard type for those in the lower economic brackets. The practice of medicine in the lower economic group becomes largely a prescription practice—a brief visit to the doctor, an inadequate, scant history, and a prescription or the dispensing of a bottle of medicine. One of the most tremendous steps

in the practice of medicine in America is that it has become a diagnostic practice, a practice based upon a complete physical examination, scientific laboratory determinations and the direct opposite of a prescription form of medical practice.

Organized medicine has improved medical standards and medical education. Improvements in medical education and the measures for protecting the community from inferior practitioners have arisen from within organized medicine. The organized medical profession, as represented by the American Medical Association, has brought about a reduction in the number of medical schools from one hundred sixty-five to sixty-seven, and succeeded in obtaining an almost uniform pre-medical curriculum, has surveyed and approved hospitals throughout the United States, has listed hospitals for the training of internes and resident internes, has promulgated a code of ethics for the protection of the public, has established certification boards for the examination and registration of those seeking to be specialists in all the major branches of medicine.

We believe (1) that all features of medical service in any method of medical practice should be under control of the medical profession. No other body or individual is legally or educationally equipped to exercise such control.

(2) That no third party should be permitted to come between the patient and his physician in any medical relation. All the responsibility for the character of medical service must be borne by the profession.

(3) That patients must have absolute freedom to choose a doctor of medicine who will serve them from among all those qualified to practice and who are willing to give service.

(4) That in whatever way the cost of medical service may be distributed, it should be paid for by the patient in accordance with his means and in a manner that is mutually satisfactory.

(5) That medical service must have no connection with any indemnity cash benefits.

The insurance principle as applied to human sickness is acceptable only in buying hospital lodging and accommodations, food, and general nursing care. The insurance principle applied to the employment of professional services will fail because there is inherent in it defects that depend upon the variability of human beings. Medical service is not a mechanical gadget that

can be fabricated. Medical service is the relationship of a doctor and a patient, and both are animated human individuals, both equipped with their own personal psychology and the character of the medical service rendered is the application of scientific knowledge plus certain intangibles to the patient's medical problem. This is not an insurance proposition that can be calculated or estimated upon an actuarial basis.

Human nature being what it is, the adoption of the insurance principle for medical services puts a premium on malingering and extension of days of illness. The average loss of time to a workman in the United States by illness is six and one-half days, in Germany under the *Krankenkasse*, thirteen days, and in England under the Panel System, eleven and one-half days. The expense of administration of sickness insurance in England amounts to over one-half of the total amount paid to the physicians, and the number of non-medical workers in Germany is greater than the total number of physicians doing the medical work.

No patient should have cash benefits for being sick. Is it reasonable to suppose that a man, being sick, not working, in a hospital, being supplied with physical accommodations, food and attention, and \$4.00 day while sick, will be anxious to return to work?

It has been estimated that to provide a comparable medical service, as exists today, on a government insurance basis, would require ten to fourteen per cent of the payroll.

We believe it is essential that the following conditions be made paramount in the consideration of medical services: (1) the maintenance of the voluntary hospital system, (2) the advance of medical science and the increasing ability of scientific medicine to serve the public in health and in disease have created new problems of medical service and medical costs. In the past, the medical profession has always been willing to give of its utmost for the care of those unable to pay. The available evidence indicates that today throughout the United States the indigent are being given a high quality of medical care and service. Nevertheless, the advances of medical science have created situations in which a group of the population, neither wholly indigent nor fully competent financially, find themselves under some circumstances unable to meet the costs of unusual medical procedures. The Board of Trustees of the American Medical Association points out the willingness of the medical profession to do its utmost today, as in the past, to provide adequate medical service for all of those unable to pay either in whole or in part. Members of the medical profession, locally, and in the various states, are ready and willing to consider other ways and means for meeting the

problems of providing medical service, and diagnostic laboratory facilities for all requiring such service, and not able to meet the full cost thereof. These are financial and administrative problems of local and state administration primarily, rather than problems of federal responsibility. The willingness of the medical profession to adjust its services so as to provide adequate medical care for all the people does not constitute in any sense of the word an endorsement of health insurance, either voluntary or compulsory, as a means of meeting the situations.

(3) Certification of indigents, fairly, sincerely, honestly and sympathetically by the application of standards of eligibility, by central bureaus under the Department of Welfare, with proper representation from the County Medical Society. It should not be the function of the out-patient departments to pass upon the validity of indigents nor should they admit for free services those who are not in truth indigents.

(4) The complete financial separation of the free out-patient departments of hospitals from the private or pay services of the hospital.

(5) Limitation of the number of patients that may attend any one clinic.

(6) Census of the indigents—to learn what the load is and how to take care of it. There should be devised a positive means of identification to prevent padding of the lists.

(7) The desirability of establishing a diagnostic laboratory service in chemistry, bacteriology and pathology for the practitioners. These laboratories to be established on a regional or geographical basis. The service to be for physicians only, and without cost. No treatment in any form to be provided under this setup.

(8) Recognizing that committees of the Senate and of the House of Representatives of the United States Government and a special committee appointed by the President are at this time concerning themselves with the reorganization of Government activities with a view to greater efficiency and economy, and recognizing also that the President, in his opening address to the Congress, indicated that he would shortly present to the Congress recommendations for such reorganization of Governmental activities in the executive branches, and recognizing moreover the great desirability that all activities of the Federal Government having to do with the promotion of health and the prevention of disease might with advantage be consolidated in one department and under one head, the Board of Trustees of the American Medical Association recommends that such health activities as now exist be so consolidated, which should not, however, be subservient to any other charitable, conservatory, or other Governmental interest.

It has been repeatedly said that public health work is the first problem of the state. It is the opinion of the Board of Trustees that health activities of the Government, except those concerned with the military establishments, should not be subservient to any other departmental interests. This reorganization and consolidation of medical departments need not, under present circumstances, involve any expansion or extension of Governmental health activities, but should serve actually to consolidate and thus to eliminate such duplications as exist. It is also the view of the Board of Trustees that the supervision and direction of such medical or health department should be in the hands of a competently trained physician, experienced in executive administration.

(9) Unequivocal opposition to all forms of compulsory health insurance. Insurance schemes tend to relieve the individual of his own responsibility and to increase the prolongation of illness. In short, under an insurance scheme it is profitable for an individual to be sick.

The medical profession "does not rely on endowment, but on its own exertions directed to meeting human wants. There is no great profession which has so little to say to the public purse, and which so moderately and modestly dips its hand into that purse. It is not only in the interest of the public, but of the profession itself, that it is eminently self-supporting, and, rely upon it, that the principle of self-support does much to maintain its honour and independence, and to enable it to pursue its stately march in the times that have come and in the times that are coming, to form its own convictions, to act upon its own principles without fear or favour, for the general benefit of mankind.

Dr Bandler in his introductory remarks announced the two-fold nature of the evening's program, the desire of the Faculty Association to honor Dr Henry Dwight Chapin who, as Professor of Pediatrics at The New York Post-Graduate Medical School and Hospital, for over fifty of his eighty years had untiringly devoted himself to that institution, and also to recount some of the accomplishments of the other members of the professional staff in the larger field of organized medicine. Of Dr Chapin he said "Dr Chapin has not only contributed to the upbuilding of an outstanding pediatric department but he has demonstrated a most unusual ability as an organizer in medicine. The establishment in our institution of the first hospital social service department in this country and the development of the Speedwell Society were the

products of Dr Chapin's fertile brain. The success of these and other outstanding sociologic organizations is due entirely to his continuous efforts and his great capacity for leadership."

Dr Arthur F Chace, President of the New York Post-Graduate Medical School and Hospital, in his address, spoke of Dr Chapin as an organizer in medicine. He said, "Medicine organizes so that it may more efficiently serve the community. Dr Chapin, individually and in cooperation with organized medicine, has served this community for five decades, efficiently, faithfully and so modestly that few realize the magnitude of his accomplishments—each year widening the scope of his energies and activities, until now he may well be called the "Dean of Social Service."

Dr Adolph G De Banctis, President of the New York County Medical Society, and Professor of Pediatrics in the New York Post-Graduate School, presented a silver loving cup to Dr Chapin on behalf of the Faculty Association, and spoke of his work as a pediatrician. He said in part

The name of Henry Dwight Chapin is synonymous with the growth of pediatrics. In the early part of the century pediatrics was a minor part of medicine, today it is a major specialty, and to Dr Chapin should go a great deal of credit for this. He is a charter member of the American Pediatric Society and one of its ex-presidents. For ten years he was president of the Children's Welfare Federation and started during that time a bureau for the distribution of mother's milk for premature babies. In 1933 Columbia University awarded him a medal for outstanding contributions to problems on child welfare.

Dr Chapin's contributions to pediatrics have been numerous and of a real and permanent value. The more important are a book of (1) "Diseases of Children" with Pisch and, later, with Royster, which has gone through three editions, (2) Acidosis of Intestinal origin, (3) Invention of the Chapin Dipper, and (4) Studies of Infant Feeding. Dr Chapin has trained many physicians in pediatrics—not a few of whom today occupy prominent positions in pediatrics. I have known Dr Chapin for over twenty years and I regard him as one of the most brilliant pediatric teachers and one of the soundest clinicians I have ever met.

The second part of the program dealt with the subject of organized medicine and the speakers of the evening were Dr Frederic E Sondern, former president of

the New York Post-Graduate Medical School and Hospital and most recent past-president of the New York State Medical Society, whose topic was "Organized Medicine and Post-graduate Medical Education," Dr Walter T Dannreuther, former president of the New York County Medical Society, and Professor of Gynecology at the Post-Graduate Medical School, who spoke on "Organized Medicine in Retrospect," and Dr Charles Gordon Heyd,

President of the American Medical Association, and professor and former director of surgery at the New York Post-Graduate

Dr Dannreuther scored the medical profession for not getting further in organized medicine and said, "Organized medicine is the logical trustee of society and the care of the public health. It must be militant but not arbitrary, positive but judicious and protective to the medical profession and zealous in behalf of the public welfare."

ALUMNI DAY MEDICAL PROGRAM

The New York University College of Medicine Alumni Association has announced through James W Smith, M.D., Secretary of the Committees on Science, Education and Entertainment, that Alumni Day will be celebrated February 20. The program is as follows:

9 45-10 00 A.M.

New Building, 28th Street and First Avenue

1 Opening remarks, Robert P Wadhams, '06, President Alumni Association.

2 Introduction, Albert A Epstein, '05, Chairman, Committee on Science and Education

10 A.M.-12 30 P.M.

1 Experience with Protamine Insulin, Elaine P Ralli, '25, Assistant Professor of Medicine

2 Diabetes as a Complication of Pregnancy, William E Studdiford, '22, Professor of Obstetrics and Gynecology

3 Diabetes in Childhood, Katharine G Dodge, Instructor in Pediatrics

4 Cardiac Complications of Diabetes, John Wyckoff, '07, Professor of Medicine

5 The Eye in Diabetes, Edward B Gresser, '22, Assistant Professor of Ophthalmology

6 Neural Complications of Diabetes, E David Friedman, '07, Professor of Neurology

Demonstrations and Exhibits, morning and afternoon, Pathological Specimens, Robert J Carlisle Memorial Exhibit, Display of books from College Library, Roentgenological Exhibit—I Seth Hirsch, Professor of Radiology

Luncheon 1 00-2 00 P.M.

Student's Lounge, 26th Street and First Avenue

Addresses of Welcome, Dean Emeritus Samuel A Brown, '94, William M Patterson, '94L, Chairman, N.Y.U. Alumni Fund, Dean John Wyckoff, '07 2 30-5 00 P.M. New Building, 28th Street and First Avenue

7 Important Aspects of Surgery in the Diabetic, Arthur Wright, Professor of Surgery, Samuel Standard, '24, Assistant Clinical Professor of Surgery

8 Anesthesia in Diabetes, Emery A Royenstine, Assistant Professor of Surgery in charge of Anesthesia

9 Preventive Treatment of Diabetic Gangrene as Carried Out in a Medical Clinic, Harold Brandaleone, '31, Assistant in Medicine

10 Pathological Findings in Diabetes, Irving Graef, Associate Professor of Pathology

5 15-6 15 P.M., Social Hour with Dean Wyckoff, Dean's Office, 28th Street Building

Informal Alumni Dinner and Entertainment, 7 00 P.M. Leo L Michel, '99, *Master of Ceremonies* Hotel Roosevelt, Madison Avenue at 45th Street

Physicians may be divided into two classes only: those who are learning and those who are forgetting: there is no third class.—Henry A Christian, M.D.

"What shall I do?" wailed the sweet young thing. "I am engaged to a man who just simply cannot bear children."

"Well," remarked the kindly old lady, "you mustn't expect too much of a husband!"—*Nebr S M Jour*

"Did you say the man was shot in the woods, doctor?"

"No, I said he was shot in the lumbar region!"—*Nebr S M Jour*

THE PHYSICIANS' HOME

A total of 208 sustaining members of the Physicians' Home has been received as a result of the effort which has been made during the last few months to impress upon physicians of the state the need to care for distressed and worthy members of the profession

Dr Charles Gordon Heyd, president of the Home, makes the announcement that the institution is now on a self-supporting basis, but that funds are still inadequate for the purposes which the board of directors have in view an adequate endowment which will allow building a permanent home to meet the requirements of the situation in New York State, where approximately 15,000 physicians are members of the Medical Society of the State of New York The response, so far, states Dr Heyd, is encouraging to the board of directors, and the efforts to augment the fund are to be continued

A number of county medical societies are making contributions to the endowment

The president is in receipt of a letter from a physician, formerly a resident of New York State for fifty-five years, who has now retired and is living in his native state The writer says

"When one considers the enormous amount of gratuitous work done by physicians it seems astounding that so little generosity is extended to those of the profession who have been superannuated and who at times are in actual want 'Man's inhumanity to man' might aptly be quoted, but I hope and must believe that concerted action by the newly constructed board of directors, may induce many who really know little or nothing

about the Physicians' Home to assist in so worthy an object as easing the last days of these benefactors of humanity Un fortunately the lay public holds to the opinion that physicians are always prosperous, that they are excessive in charges for service, and are really no more deserving than others of the human family They know little concerning the pedestal to which men of medicine have been elevated by great writers of all ages, and despite such praise it seems difficult to interest even our own profession in the men who so often have devoted a lifetime to the well-being of their fellows

"Having provided for my own terminal needs, I shall never have to appeal to the Home, as a beneficiary, but proud of my profession, I feel deeply the needs of those members who have become dependent. May your efforts and those of your board meet success and may you establish a *real* refuge for worn-out members of the greatest profession on earth "

The Home is now prepared to accept a few more guests

Doctors are asked to make the check payable to the Physicians' Home and mail it to Dr B Wallace Hamilton, treasurer, 52 East 66 Street, New York City

Annual Member, \$10 or more, Sustaining Member, \$100 to \$1,000, Life Member, \$1,000 to \$5,000, Patron, \$5,000 to \$10,000, Benefactor, \$10,000 or more

Officers of the Physicians' Home include Dr Charles Gordon Heyd, president, Dr Warren Coleman, 1st vice-president, Dr Silas F Hallock, 2d vice-president, Dr B Wallace Hamilton, treasurer, and Dr Joseph J Eller, secretary

As houses well stored with provisions are likely to be full of mice, so the bodies of

those that eat much are full of diseases—
Diogenes

Medical News

Secretaries of County and local Medical Societies are requested to send the programs of coming meetings to this department one month in advance, for the information of members who may be interested

Albany County

THE JANUARY MEETING of the Medical Society of the County of Albany was held in the Auditorium of the Albany College of Pharmacy, January 27. The scientific program "Recent Concepts of Treatment of Acute and Chronic Arthritis," by Dr. R. Garfield Snyder, F.A.C.P., Chief of the Arthritis Service, Hospital for Ruptured and Crippled, New York City. Discussion was opened by Dr. L. Whittington Gorham.

Chenango County

DR. EARL W. WILCOX, of Norwich, a past president of the Chenango Medical Society, died on Jan. 6. He was sixty-four.

Columbia County

DR. HENRY J. NOERLING, of Valatie, has been elected president of the Columbia County Board of Health.

Dutchess County

DR. HOWARD P. CARPENTER, deputy county medical examiner and pathologist at the Hudson River State hospital, was elected secretary-treasurer of the Dutchess County Medical Society for his twenty-second term when members convened in annual session at St. Francis' hospital on Jan. 13.

Dr. Chester O. Davison was elected president of the society, Dr. Harry E. Storrs of the Wassauc State hospital, vice president, Dr. John F. Rogers, associate secretary, Dr. Alva L. Peckham, Dr. E. F. Powell, and Dr. James J. Toomey, censors, Dr. Aaron Sobel, delegate to the state society, Dr. Samuel Appel, county medical examiner, alternate, and Mayor Spratt, counselor.

Guest speaker at the meeting was Dr. Frank Lahey, surgeon of Boston, Mass., who gave an interesting talk on diseases of the gall bladder. Prior to the meeting he was guest at a dinner given by officers of the society at the Amrita club.

Erie County

DR. ALFRED W. BAYLISS, of Buffalo, who died on Jan. 11 at the age of eighty-two, was

one of the first radiologists in Western New York. He studied electrotherapy and radiology in New York, Philadelphia, London, Heidelberg, and Paris.

Jefferson County

THE JEFFERSON COUNTY Medical Society met on Jan. 14 at the Black River Valley club. The program was a comprehensive discussion of the medical economic situation, together with compensation work. The speaker was Dr. Frederick S. Wetherell, a member of the committee on economics of the state medical society. He spoke on "A Survey of the Medical Economic Situation."

Kings County

SOUTH BROOKLYN DOCTORS have embarked on their own campaign to thwart spread of influenza and other respiratory diseases such as common cold, pneumonia and tuberculosis.

They have opened a school at Prospect Branch of the Y.M.C.A., 357 9th St., at which storekeepers are taught, free of charge, rudiments of hygiene and sterilization. Classes have begun under direction of Dr. P. J. Imperato, member of the South Brooklyn Medical Society, and any food-handler will be welcomed as a student and recruit in the war against sickness.

The idea for such instruction followed a series of special studies by the society. Despite stringent city laws diseases are still being transferred from sick to healthy persons in ice cream parlors, lunchrooms and candy stores where glasses, dishes and utensils are not sterilized.

Dr. Imperato explains:

"We believe that the majority of men and women behind the counters, although not deliberately careless, have never been taught how to sterilize or even thoroughly cleanse the articles and do not know the fundamental principles of hygiene or anything about germs and their transmission by unclean utensils."

AT A MEETING OF THE Woman's Auxiliary of the Medical Society of the County of Kings on Jan. 12, Dr. Paul C. Eschweiler was the guest speaker. Mrs. Kenneth J. Hollinshead spoke on the "Value of the

Visiting Nurse" After the discussion Mrs Edwin A Griffin, president, presided at the tea table

IT IS HOPED to continue the "movie clinics" that were started by the Kings County Society last year, and the committee, in an appeal, "asks the clinicians of Brooklyn to send in movies of diagnostic value which can be used singly or in combination" Over 200 members have expressed interest in a new series

THE SPRING SERIES of Friday afternoon lectures is now under way at the MacNaughton Auditorium On March 5 at 4 30 Dr Ernest E Boas of New York City will talk on the "Home Medical Care of the Chronic Sick" Dr Boas is a member of the Welfare Council of the City of New York

Dr Frederick S Wetherell will be the speaker on March 12 He will present "Care of Hand Injuries by the Family Physician" In view of the new compensation law, Dr Wetherell's talk should be of special value

There will be seven additional lectures in this Spring Series

Monroe County

A GAIT MEASURING device developed at the University of Rochester School of Medicine has brought the gold award of the American Academy of Orthopedic Surgeons to Dr R Plato Schwartz and his associates Known as an electro-basograph, it is an instrument to detect irregularities in the gait of a subject as he walks across a platform, and aids in studying deviations from a normal stride that may indicate the presence of brain tumors

BETWEEN 400 AND 500 Rochester medical men attended a special meeting of the Medical Society on Jan 13 to hear Dr Raymond Aloysius Vonderlehr, assistant surgeon general of the United States Public Health Bureau, on the nation-wide campaign to eradicate anti-social diseases Lectures on laboratory diagnosis and fever therapy, accompanied by motion pictures, were given at the meeting Dr Vonderlehr spent the day conferring with interested local physicians

Nassau County

CALLING ATTENTION to the fact that two-thirds of the school children in Nassau county are now protected against diphtheria, the Nassau County Medical Society states in its news bulletin that the profession

should be highly gratified with the "spectacular" record during the eight year drive conducted by the physicians

The article points out that in 1928 when the program was begun 208 cases of diphtheria were reported in the county with twelve deaths In 1934 the lowest point was reached when twenty-two cases and one death were reported

New York County

DR. ISIDORE WENGRAF, sixty-two, physician for fake accident claim ring, was sentenced to thirty days in the Workhouse in Special Sessions on Jan 13 He pleaded guilty to conspiracy to commit grand larceny on Dec 17 Dr Wengraf was alleged to have issued medical certificates of injury in thirty-five cases He was an employee of the Board of Health for twenty-two years In passing sentence on the physician, the court said it was showing consideration for his age and length of service with the Board of Health

Oneida County

DR WILLIAM HALE JR was elected president of the Oneida County Medical Society to succeed Dr Dan Mellen at the annual meeting in Utica on Jan 12 Dr Hale served as secretary of the organization for fourteen years

Other officers named are Dr H N Squier, vice-president, Dr James I Farrell, secretary, Dr H D MacFarland, treasurer, Dr T Wood Clarke, librarian

On the board of censors are Drs Mellen, W N Roemer, F J Rossi, Paul P Gregory, and J B Lawler Delegates chosen to the state society are Drs Hale and E. E. Powers, alternates, Drs M D Graham and A F Gaffney

Dr Mellen read a paper on the life of Louis Pasteur, Dr James E Gage reported on the Workmen's Compensation Board and Dr F M Miller on the Workmen's Compensation Arbitration Board

The county society was complimented by Dr Joseph Lawrence, on co-operating in the Institute for Public Education on Syphilis Control to be conducted He also reviewed legislation and said the public is becoming better educated along medical lines

Onondaga County

RESPONSIBILITY FOR THE TASK of reducing the county's high maternal mortality rate was placed jointly before physicians and public as Onondaga County's maternal wel-

fare campaign got under way. The drive was launched at a dinner meeting in Hotel Syracuse on Jan 13 when widely known physicians called on public support of the drive to lower the national death rate through wide publicity, educational programs, establishment of pre-natal clinics and hospital residencies. Sponsored by the maternal welfare committee of the Onondaga Medical Society, the meeting was attended by several hundred doctors and men and women of the county, who pledged their support of the drive.

Ontario County

FORTY-EIGHT MEMBERS and guests of the Ontario County Medical Society met on Jan 12 in Thompson Memorial Hospital for the first quarterly meeting of the year. Dr C W Grove, new president, conducted the business session, which was followed by a turkey dinner and the program. Dr Arthur Hilton Paine gave the address on "Hematuria." Announcement was made that the Geneva doctors would be hosts at the next meeting, April 13.

Queens County

THE PROGRAM of the Medical Society of the County of Queens, on January 26, included "The Operation of the Compensation Law" by Elmer F Andrews, Industrial Commissioner of the Department of Labor of the State. "Coordination of the Workmen's Compensation Law with the Practice of Medicine," by David J Kaliski, M D, Chairman, Committee on Workmen's Compensation of the Medical Society of the State of New York. "The Practical Application of the Workmen's Compensation Law," by Joseph Wrana, M D, Chairman, Workmen's Compensation Committee of the Medical Society of the County of Queens, Inc.

Rensselaer County

THE RENSSELAER COUNTY Medical Society began its 1937 program of scientific and social meetings on Jan 12 at the Health Center at Troy with Dr Stephen H Curtis, the new president, in charge. Several papers dealing with interesting cases were read. Dr C F Kivlin presented a report on "A Case of Hematocele of the Cervix." Another rare case of "Double Kidney" was reported upon and illustrated by Drs. H P Howd and D E Rowan. Dr W B D Van Aulen, retiring president, gave an address on "Economic Problems in Medicine." Forum discussions were conducted after each scientific paper.

Rockland County

THE WOMAN'S AUXILIARY of the Rockland County Medical Society held its fourth meeting, a luncheon meeting, at the Woman's Club in Suffern on Jan 13. Mrs S W S Toms of Nyack, president of the organization, welcomed the new members. Mrs J K Pettit of Thiells invited the women to hold their next meeting at Letchworth Village on Wednesday, March 10.

Schenectady County

DR WILLIAM C TREDER, Schenectady county coroner since 1921 and health officer of Glenville for the past twenty-four years, was named commissioner of public health of Schenectady on Jan 15 by City Manager Leroy C Purdy. The appointment requires the full time of the incumbent and carries a salary of \$7,000.

Sullivan County

DR B P STIVELMAN of New York City addressed the society on "Clinical Manifestation of Pulmonary Neoplasm," at the last meeting, January 20.

The next meeting is scheduled to be held in the Lenape Hotel in Liberty on February 24 at 8 30 P M. At that time Dr Edward S Rogers, Director, Bureau of Pneumonia Control, New York State Department of Health, will talk to the society.

Arrangements of a Postgraduate course in Orthopedic Surgery under the direction of Dr Leo B Mayer for the months of March and April have been completed.

Washington County

DR DENVER M VICKERS, Secretary, reports that on January 14 there was held at the Mary McClellan Hospital at Cambridge, a combined meeting of the staff of the hospital, and the quarterly meeting of the Washington County Medical Society. The first speaker was Dr Bradley L Coley of New York City, son of the late William B Coley, long associated with the hospital. Dr Coley spoke on "The Diagnosis and Treatment of Hernia."

Westchester County

THE MEDICAL SOCIETY of the County of Westchester adopted a resolution at its meeting on Jan 19 urging the American Medical Association to set up a public relations department to combat efforts to establish compulsory health insurance.

Hospital News

Injurious Effects of Hospital Lotteries

HOSPITAL LOTTERIES HAVE BEEN exhaustively investigated by a commission appointed by the government of South Australia, and the conclusion reached is that such lotteries exploit the gullibility of the public, demoralize governments, and do not help reduce the government expenditure for hospitals to any real extent. The commission secured all possible information about such lotteries now operating in New South Wales, Queensland, Tasmania, Ireland, France, and other countries, and has made its report, which is summarized in a letter to the *A.M.A. Journal*.

The commission gained the definite impression that lotteries conducted on the lines of those of New South Wales, Queensland and Tasmania tend to become the masters rather than the servants of the government that "controls" them. The commission considered that the state of affairs tends to demoralize governments. After full and careful investigation the commission satisfied itself that the lottery does not and cannot solve the hospital finance problem. Even in Ireland the immense Irish sweep has not relieved the government or the local authorities of their hospital obligations, and in Western Australia and in Queensland lotteries have not helped the government to any material extent. The existence of lotteries in four of the six Australian states, and the seeming benefits derived from them, give an impression that a lottery is desirable. After thorough investigation, however, the commission is satisfied that these benefits are more superficial than real.

Some reasons why lotteries do not relieve the government financial expenditure are

that the great publicity makes the people "hospital minded," and they demand more accommodation, more hospitals, and better buildings and equipment, while at the same time the people who formerly gave money to hospitals stop their contributions as no longer needed. Thus in fact "the ultimate burden is likely to be increased by the existence of a lottery."

And what is worse, "everywhere the lottery is an exploitation of the gullibility of the public and the widespread gambling instinct." The commission concluded that a lottery as a form of hospital finance provides an unstable method that is demoralizing to the government, distinctly injurious to traders and detrimental in the end to the poorer sections of the community, who contribute the bulk of the receipts. If the people who buy lottery tickets can easily afford the money, they can afford to pay their share of the direct taxation necessary to support hospitals. If they cannot afford the money, the state should not take their money. From the establishment of the "golden casket" in Queensland nearly twenty years ago the total receipts amounted to £12,000,000, the prize money amounted to £7,000,000 and the sum paid to hospitals and charities after payment of expenses was £3,000,000. These figures confirm the commission in its belief that the lottery does not and cannot solve the hospital finance problem and consequently it was recommended that the practice should not be permitted in South Australia.

Air-Conditioned Operating Rooms

AIR-CONDITIONING "IS INDEED a godsend," is the conclusion of a southern medical editor after a year's experience. He writes about it in *Southern Medicine and Surgery* and tells what it has done in a hospital at Columbia, S. C. As we read

In midsummer of last year [1935] air-conditioning was installed in the operating rooms of the Columbia Hospital. After a year's experience one should have a definite impression of its benefits and of its disadvantages, if any. The sterilizing room is immediately between the

two major operating rooms on the top floor and is without a hood or overhead vent for the hot air and escaping steam, although there is an outside window. The operating rooms have large skylights through which the hot summer sun shines. Neither the sterilizing room nor the operating rooms have adequate through-and-through ventilation, so the humidity is even more of a problem than the heat. So it comes to pass that, with an outside temperature of 100° F., the working conditions in the operating room are almost unbearable.

Air-conditioning, as here used, shall be con

sidered as it affects the patient, the surgeon, and the operating room nurses. With the temperature of the operating room uniformly kept at 80° F the patient experiences an exhilaration on entering, sweating stops, respirations are deeper and slower. The skin through which the incision is made is dry so that the antiseptic preparation is more effective, it stays dry during the operation so that aseptic technic can be better preserved. A local internist at first thought that pneumonia might be caused by the sudden entrance of a lightly clad patient already ill and with poor resistance into an atmosphere 20° F less than that to which he had been accustomed. He thought that shock might be greater because of the lowered temperature. Experience has proved both fears groundless. On the contrary, the patient seems to get increased vitality from the lowered room temperature.

In hot weather the comfort of the surgeon working in an air-conditioned room is infinitely greater. His body is no longer drenched in sweat. His face and neck are dry and do not

have to be constantly mopped to keep the sweat from dripping upon the dressings or the wound. He does his work with greater safety, with more facility, and with less fatigue. The greatest benefit of air-conditioning is experienced in operations at night. Heretofore gnats and bugs, attracted by the light, have come through the window screens almost with impunity, so that the windows had to be kept closed while the lights were on. Now the room may be kept comfortable even with the windows closed.

It is a biologic fact that white women do not stand the heat and humidity of the tropics well. Both of these are more severe in summer in the unconditioned operating room in this climate than in the tropics. The nurses when on operating-room duty in summer in Columbia, almost without exception, lose weight and color. They have to be shifted often. The surgeon spend a comparatively short time in the operating room but the nurses spend their working hours there. To them air-conditioning is indeed a godsend.

A Bed of New Design

THE MEDICAL SUPERINTENDENT of a large hospital in Wales has designed a bed which he believes has its points of advantage. He is Dr Melbourne Thomas, superintendent of Llynypia Hospital at Rhondda, and he describes and pictures it in the *British Medical Journal* of Jan. 2. He writes:

The bed-frame about to be described was built after long residential experience in hospital had taught me something of the value, in convalescence, of muscular relaxation and postural comfort. I do not think the importance of these factors in convalescence is commonly or sufficiently appreciated. They are worthy of elaboration, but this is outside the scope of this communication. Furthermore, I believe that patients often leave a bed at home to enter a less comfortable one in hospital.

These observations stimulated me to design the bed-frame illustrated, wherein the shortcomings of the bedstead as commonly designed have been minimized in the following ways:

(1) causing the buttocks to rest in a _/_/

shaped interval in place of the customary V shaped interval, (2) supporting the proximal two-thirds of the thighs in place of the knee-joints, (3) providing a foot-rest, and that at a variable inclination. No 1 results in greater comfort to the lumbar region—a point of considerable importance—and prevents the usual tendency in a weak patient to gravitate towards the foot-end. No 3 gives the patient a feeling of postural security, prevents the tendency to plantar flexion at the ankle-joint, and relieves the toes of the weight of bedclothes.

The bed is further designed to accommodate comfortably either a tall or a short patient. The designs have been implemented by the makers with a simple and neat mechanism, which appears durable and is easily worked by a nurse. I recommend the bedstead to be used in conjunction with a sponge-rubber mattress. Experience of the use of this bedstead with a variety of patients in the sick wards has confirmed what was expected of it. It gives, I believe, to the patient a degree of comfort hitherto unavailable.

Improvements

CONSTRUCTION WORK on the new Bronx Eye and Ear Infirmary has reached the point where the finishing touches are being put to the foundations. Officials expect the structure to be completed in July or August. The new building will cost in the neighborhood of \$200,000. The infirmary is devoted exclusively to eye, ear, nose and throat cases. Its present quarters at 459 E 141st St, near

Willis Ave, have long been overcrowded and outmoded.

• • •

OSSINING HOSPITAL IS RAISING funds for a new ambulance. To aid the campaign, local physicians are making rather blistering comments on the old one now in use. Such exclamations as "It's terrible!" "It's a menace!" "It's a relic and a disgrace!" are

quoted in the Ossining papers. One doctor remarks that he "would rather walk to the hospital with a broken leg than ride in our ambulance." Funds are reported coming in rapidly.

• • •

DEPUTY CONTROLLER Milton Solomon surprised 1,000 diners at the annual ball of the Jewish Sanitarium and Hospital for Chronic Diseases in the grand ballroom of the Hotel St. George in Brooklyn on Jan. 11 by announcing a plan to add a new wing to the hospital building at E. 49th St. and Rutland Road to care for 500 juvenile sufferers from infantile paralysis and related diseases. It will be paid for by a newly organized men's club. The men's club has 200 members, and will launch an immediate drive to add 5,000 names.

• • •

THE COHOES HOSPITAL has just opened a new \$25,000 operating room.

• • •

START OF A MODERN HOSPITAL at Liberty within a year, eventually to replace the existing structure and to give to the community an establishment equal to any in a locality of similar size in the state, was forecast on Jan. 3 at the eleventh annual dinner of Maimonides Hospital at the Grossinger Country Club at Ferndale. The prediction was made by Charles Golembe, president of the hospital association, to the more than 300 assembled in the main dining room of the county's largest resort hotel.

• • •

THE JUNIOR AUXILIARY to the Flushing Hospital is planning to install a new lighting equipment as its gift to the hospital. Mrs. Hildegard Gustafson has been elected president of the Auxiliary. A card party will be held March 19 in the Nurses Home to help raise funds.

• • •

SENECA FALLS HOSPITAL is starting a

campaign for a much needed enlargement.

• • •

A FOUR-STORY BRICK ANNEX is to be added to the Madison Park Hospital, in Brooklyn, at a cost of \$250,000. The building will occupy a plot 100 feet on Kings Highway and 80 feet on E. 26th St. and harmonize with the present structure.

• • •

NASSAU COUNTY PLANS to spend \$225,000 to build an addition to the contagious disease section of the Meadowbrook General Hospital and \$75,000 for repairs and improvements to the county sanatorium at Farmingdale. The hospital wing will contain additional facilities for handling contagious diseases and tumor clinic cases, permitting use of main hospital beds for other cases. Improvements at the sanatorium include repairs to some of the buildings upwards of sixteen years old, in addition to various minor alterations.

• • •

PLANS HAVE BEEN FILED for an annex to Beth-El Hospital in Brooklyn to cost \$500,000. The building will be five stories in height and conform to the architecture of the main hospital. The new section will be used as the maternity unit. The plans prepared by S. M. Malkind, architect, provide for remodeling of the old building.

• • •

ARMAND VINCENT, CANADIAN sports promoter, has leased the Polo Grounds for a three-day international winter sports carnival and ski meet on the afternoon and evenings of February 20, 21, 22. The Warm Springs Foundation and a committee, including Governor Lehman and Mayor La Guardia, organized to build two therapeutic pools in public hospitals, will share in the receipts. The three-day program will include ski jumping, slalom racing, snowshoe racing and dog sled racing. The field and ski jump will be covered with six inches of snow produced by machines cutting up ice into flakes.

Events

THE PROCEEDS OF THE polo tournament of the New York Athletic Association at the 105th Field Artillery Armory, Manhattan, on February 13, were devoted to the sick poor at the Flower-Fifth Ave. Hospital.

SIMULATED SNOW, dazzling ice and prismatic crystal effects transformed the main ballroom of the Waldorf-Astoria into a Winter setting for the annual snow ball for the benefit of the Lenox Hill Hospital on

the night of Jan 20 under the auspices of the Ladies Aid Society of the hospital

• • •

THE STAFF BALL OF MERCY Hospital in Buffalo was held on Jan 16

• • •

THE ROSEDALE WOMEN'S CLUB gave a luncheon and card party on Jan 13, the proceeds going to refurbish a room in the Jamaica Hospital

• • •

THE SEVENTEENTH ANNUAL DINNER of the trustees and professional staff of the Car-

son C Peck Memorial Hospital of Brooklyn was held on Jan 9

• • •

A DINNER DANCE for the benefit of the Lutheran Hospital of Brooklyn was given on Feb 4 at the Towers Hotel. The proceeds will go for new equipment

• • •

WHILE MORE THAN 200 persons watched ground was broken for the three-story and basement brick annex to the four-story Evangelical Deaconess Hospital in Brooklyn. The Rev August D Pfost, superintendent, turned the first shovelfull of dirt

Newsy Notes

THE SOLDIERS AND SAILORS Memorial Hospital, of Penn Yann, is now free of debt, President Andrews announced at the annual meeting in January. "Starting at \$50,000," he continued, "the mortgage has gradually been reduced until on November 10 1936, we made the last payment. As a sidelight, I might mention that the interest paid during these eleven years on the mortgage amounted to more than \$22,000, or almost half of the original principal." Constructed at a cost of \$175,000, the hospital is the only one in Yates county

• • •

WILLIAMSBURG RESIDENTS have begun a campaign to reopen the old Eastern District Hospital in South Third St., Brooklyn. The red brick structure, between Driggs and Bedford Aves., is reported in fairly good condition and with simple repairs might again serve the community

• • •

THE J N ADAMS MEMORIAL Hospital has reported to the Buffalo Common Council that it is impossible to obtain internes at the low fixed pay of \$600 a year. The Council has been asked by the health board to create the post of junior physician at the hospital

• • •

THE IMMEDIATE CREATION of a free clinic at the Meadowbrook general hospital to handle social diseases is one of the pressing health needs of the county, Dr Wil-

liam H Runcie, town of Hempstead health officer, told members of the town board on Jan 5

Stating that officials of the general county hospital are at present reluctant to handle these cases, Dr Runcie advised town officials that conditions have now reached a point where the matter will have to be given consideration as a vital health menace

• • •

FOR THE FIRST TIME since it was constructed in 1898, Pavilion C at Albany Hospital is to be remodeled. The program calls for the expenditure of \$21,000 for a thermostatically controlled heating system, modern gas facilities, new electric wiring, adequate reading lights for every patient, new treatment rooms, utility rooms and diet kitchens, one double and two single recovery rooms on each floor and increased storage space

• • •

THERE WERE 689 babies born in Mount Vernon Hospital in 1936, an increase of twenty over the previous year, according to a report filed with the Board of Managers by Superintendent Mary A Land. There were 4,586 patients treated in 1936 as compared with 4,438 in 1935, an increase of 148. The average number of patients in the hospital each day of 1936 was 126 against 120 in 1935. First aid treatment was given 5,316 persons during the year just closed, against 5,203 in 1935. Opera-

tions increased last year, with 2,631 against 2,523 in 1935

Counsel, Medical Society of the State of New York

Unlicensed Practitioners—Unlawful Practice of Medicine

The question of the extent to which the penal statutes can be used to effectively curb the activities of irregular practitioners of medicine was the subject of a decision recently made in one of the states of the midwest*

Two charges were brought against the defendant N, the first being that he had unlawfully treated the sick without a certificate of registration in the basic sciences, and the second being that he had unlawfully assumed the title of Doctor

The Statute involved specified that "No person shall treat, or attempt to treat, the sick unless he shall have a certificate of registration in the basic sciences" "Treating the sick" was defined by law as follows

To "treat the sick" is to examine into the fact, condition, or cause of human health or disease, or to treat, operate, prescribe or advise for the same, or to undertake, offer, advertise, announce or hold out in any manner to do any of said acts, for compensation, direct or indirect, or in the expectation thereof

Disease by law was defined to include "any pain, injury, deformity, or physical or mental illness or departure from complete health and proper condition of the human body or any of its parts"

Upon the trial it was conceded that N was not licensed within the State to practice medicine or optometry and that he had no certificate of registration in the basic sciences. It was contended, however, on his behalf that the acts which formed the State's case against him amounted to no violation of law, and that at most he had prescribed exercises for physical culture purposes

From the testimony upon the trial it appeared that N was sales manager for a corporation called "The American Society for the Conservation of Vision." It conducted a suite of offices with the corporate name on the door and under that a name reading "James L. H., M.D." Three individuals who consulted N at those offices and received treatment gave their version of his activities

It seems that a Miss A and a Mrs B entered the office together and were both

told by an office girl, "This is Dr N and he'll take care of you" N told the two prospective patients to follow him into another room where he examined their eyes with an ophthalmoscope and noted their vision by means of lettered charts. He told both of the women that their trouble was astigmatism. Miss A told N that she suffered from sick headaches when she did not use glasses. She was told that N would reduce the strength of her lenses, and would also give her a series of eighteen treatments after which he told her she would be able to go without glasses, and her headaches would be cured. Mrs B was told that she would not need glasses after twelve of his treatments. On that day he gave instructions to Miss A as to the use of heating pads for her headaches

The next day the two women returned to N's office, according to the testimony. He gave each of them charts with dots and lettering and instructed them as to a method of looking at the dots from various angles, and as to how to exercise their eyes daily in other manners. He told Mrs B to leave her glasses off, stating that if she wore them she would undo the good accomplished by his method of treatment. She complained that if her glasses were left off she would have headaches and was told to ignore such headaches, since with successive treatment the headaches would be gone. N named as a price for his services \$5 00 for each treatment or six treatments for \$25 00, and requested each of them to pay \$5 00 to his office girl. They did so and each received a receipt

The third witness who gave testimony concerning treatment was C, a man who was afflicted with a partial paralysis described as being sometimes called the blind staggers. He also sought N's services regarding the condition of his eyes. N advised C that his difficulty could be corrected by exercises, and that he would eventually be able to go without glasses, after various changes were made in his lenses to lessen their strength by degrees. N stood C before a chart and directed movements of C's head in reading the chart, and gave him directions as to methods of home exercise

*Nickell v State, 238 N W 508

The second charge against N was based upon violation of the statute providing

No person not possessing a license to practice medicine and surgery, osteopathy, or osteopathy and surgery, shall use or assume the title "doctor" or append to his name the words or letters "doctor," "Dr," "specialist," "M D," "D O" or any other title, letters or designation which represents or may tend to represent him as a doctor in any branch of treating the sick.

In the support of the second charge in addition to the testimony already referred to, it was shown that when introduced to Miss A and Mrs B as Dr N he promptly proceeded to treat them, doing nothing to correct the erroneous impression that he was "Dr" N. It was also shown that when a few days later one D an investigator for the State Board of Medical Examiners called at his office and asked him if he was Dr N he had replied, "Yes, sir, I am."

Upon such proof N was found guilty by a jury upon both of the charges and was duly sentenced. He, however, appealed the matter to the highest State Court, claiming that the evidence failed to sustain either of the charges. The Appellate Court affirmed the conviction, and in the course of the opinion stated

That evidence was certainly ample to establish that N on or about February 6, 1931, in violation of section 147.02 Stats, for compensation unlawfully did treat the sick as that term is defined. The astigmatism and headaches of Miss A and Mrs B, and the partial paralysis of C, constituted a disease.

The manner in which he examined their eyes, and into the condition and causes of their respective diseases, and thereupon treated and

prescribed and advised treatment for those conditions, and held out that by such treatment their diseases and conditions, including their sight, would be remedied, clearly constituted treating the sick. The attending circumstances and manner in which the examinations were made, the character of the treatments prescribed and given, and the accompanying advice as to their necessity and purpose and the prophesied remedial achievements, were such that it would be ridiculous to consider the treatments mere ocular calisthenics on a par with the exercises customarily prescribed for ordinary physical culture purposes. The conviction on the first charge was well-warranted by the evidence."

In connection with the second charge the Court said

"In view of the circumstances and transactions at that office on February 5, 6, and 7, 1931, in which N participated, it was within the province of the jury to find, under the evidence, that N on or about February 6, 1931, did assume the title "doctor" in a way that tended to represent him as doctor in a branch of treating the sick, and consequently, as he did not then possess a license to practice he was guilty as charged. From what was then said by others in N's hearing, and his conduct and statements in immediate response thereto, the jury could rightly infer that he did then adopt, take upon himself, feign, affect or pretend to possess that title. Manifestly, in answering "Yes, sir, I am," to D's question whether he was "Dr N" he affirmed that title. Less convincing to some degree but equally misleading and deceptive was his silence when, upon hearing that title falsely applied to himself by a subordinate employee, he responded thereto, and as in response thereto, adopted and took that title upon himself by affecting and pretending to have the knowledge, skill, and legal privilege to treat the sick, which that title implied under the existing circumstances."

PURE FOOD AND DRUG FIGHT RENEWED

Senator Copeland is renewing his fight for his pure food and drug bill in the new session of the Senate, and a similar measure is being introduced in the House. According to accounts in Washington newspapers, the new Copeland measure will contain the same principal provisions as the bill shelved in the last Congress because of strong opposition to some of the regulatory measures governing labeling and packing of foods, drugs and cosmetics.

In addition, Dr Copeland said, it will contain revised provisions for strengthening the enforcement features of the Wiley law, create uniform standards of identity and quality, and "outlaw the manufactures of fakes." He added

"The primary purpose of the bill is to protect the consumer, of course, but there must be regulations also to protect the manufacturer.

"Much progress has been made in the food industry since the enactment of the Wiley law, but it should be brought up to date with the progress that has been made during that time."

Dr Copeland added that much of the opposition heretofore expressed to the Wiley law is diminishing.

"It is interesting to note that many manufacturers who opposed the 1906 law have become its most ardent champions."

Across the Desk

Are Our Brains Getting Tougher?

SOME TIME AGO the story was told in these columns of a young woman out in California who fired a bullet through her brain and injured herself so badly that it was really several weeks before she was out of the hospital and several months before she was around doing her household duties as usual

She made only one try True, the one shot rendered her unconscious for a time, but she has not repeated the experiment since, as far as reported. In that she is different from an Englishman who decided a few days before Christmas that he couldn't stand our delightful world any longer, and placed a revolver to the side of his head and pulled the trigger The bullet entered his brain and came out on the other side all right, but the man was not even stunned. We can imagine him looking at the revolver and wondering if he had been cheated. Perhaps it was an inferior make Or maybe he was doing it wrong Anyway, we know that he changed it over to the other hand, held it to the other side of his head, and got the desired result.

Dr Joan Ross, pathologist, testifying at the inquest, said there was one wound on each side of the head The first bullet was found to have passed through the brain without causing any vital or extensive injury, and evidently did not cause unconsciousness The second did the trick.

Something is seemingly wrong with our brains or our bullets It was not thus in the olden days In fact, the famous so-called "intelligence" tests, faced by our fearless army in the war, had one supposedly absurd sentence about a man, shot twice in the head, who was thought to have killed himself Impossible! Yet it happened in England in December

Fiction that is Stranger than Truth

"Dogged does it," is an English saying

"If at first you don't succeed, try, try again" So he deftly shifted his weapon to the other hand, and in a moment he received his harp, coal shovel or whatever, as the Scotch say He was more successful, anyway, than the man in the old story who had failed in everything, decided to end his life "and all," and was determined not to fail in that, at any rate, so he went out on the river in a boat, found a tree overhanging the water, tied a rope to a branch and the end around his neck, swallowed a dose of poison, kicked the boat from under him, put a pistol to his head, and fired Never a crack shot, his bullet missed and cut the rope, he fell in the river, swallowed a lot of water, which made him feel sick, as he was not used to drinking water, brought up the poison, then the sheriff happened along, dragged him out, and arrested him for violating the bathing regulations

The Bad Die Young

A lynx-eyed reader recently criticized this scribe for printing a story that was four or five weeks old The writer took it really as a bouquet, for he recalled the saying of a wise old professor in an Eastern university that if a story were not good, it would never get to be old Well, the reason he tells this one is that it is so old that the middle-aged and younger members of our reading circle probably never heard it. It dates back to around the McKinley Administration Any one who has the temerity to write in and criticize it, well, he dates himself, he dates himself Will that make him feel small? Maybe If not, we note a warning statement in the *News Letter* of the Suffolk County Medical Society that "Harvard scientists have found a way to shave fossils to a thickness of only 1-25,000 of an inch" Why, is not stated, but there you are Beware

Our Auxiliaries—The Next Step?

THE RAPID ORGANIZATION of women's auxiliaries to the county medical societies goes merrily on They will soon be a powerful force, aiding in ways that only the feminine

touch can bring And it is not saying anything treasonable or even heterodox to declare that they are going to get a lot more of fun out of their gatherings than their

men do out of their conclaves. Nothing has been reported to this scribe, so far about any magazine or news sheet to be the voice of the New York State Auxiliaries. Some other states have publications of this kind which pay for themselves by their advertising and afford the members a chance to express their views, record their doings, and get acquainted generally through the chit-chat of the printed page.

It happens that the "Woman's Auxiliary Section" of the *Kentucky Medical Journal* has just come to this desk. It is a quarterly publication, and is produced by two groups of the auxiliary members, known as the "Cornelias" and the "Isabellas." The Cornelias, it seems, are the members who write, edit and prepare the reading matter, and the Isabellas look after the financial end. The Isabellas sell the advertising space, and we are given a vivid word picture of an Isabella interviewing the head of a business firm, displaying a copy of the quarterly, then handing him a rate sheet, and finally the Contract Blank, pointing out the Dotted Line which he is to grace with his signature. The scene closes on a note of charm, the Isabella "gratefully accepting the check" and taking it to the Business Manager.

Auxiliaries in the Flood Crisis

A more serious reflection is that these

devoted wives of the Kentucky medical men are probably now having their hearts and hands more than full in the service of the sick and suffering in the tragical floods inundating their river towns and cities. This is a crisis when the auxiliaries, with many of their members skilled in the care of the sick, can turn in a moment from social doings to render splendid service, and we can readily imagine the Isabellas and the Cornelias and all their sisters helping grandly in the work of succor, or, equally invaluable, keeping their men in trim for their night and day battle with disease and death.

The fifth birthday of the quarterly was recently celebrated at a dinner party of the Isabellas, shown in a flashlight photograph, with the winning smiles to which the big business executives succumbed. We are assured that some of the stories of their interviews would have made good material for O Henry. The Cornelias are seen in another picture preparing the material for the printer, and typing a letter of instructions. A good companion picture would have been a snap-shot of the same faithful workers, on the day after publication, typing a warmish letter to the printer asking a few pointed questions about how it happened that this and that error crept into the types! For such is the way of all journalism.

A Happily Groundless Scare

A NEWS ARTICLE the other day told of an enterprising concern in New York City that is achieving prosperity by cleaning and sterilizing the mouthpieces of telephone instruments in offices where the bosses are germ-conscious, so to speak. A vivid sales-talk, with pictures of horrid-looking bacilli, no doubt can throw the most hard-boiled executive into a cold sweat and make the goose-pimples rise all over him. The signing of a nice little contract to disinfect the mouthpiece, at so much per, follows in two minutes.

Not a word is to be said against such a campaign. If we had cleanliness everywhere, disease would be reduced enormously. Clean and sterilize the mouthpieces, by all means. But, at the same time, the medical profession and the public are entitled to know the facts, and people should not be thrown into a panic and be frightened away from using

public telephones when there is really no danger. No good purpose could be served by that.

Fortunately we have a report of an exhaustive investigation of this very matter by Prof. Ludwig Lange at the German National Health Bureau Laboratory for Experimental Research on Tuberculosis, and reported in a Berlin letter to the *Journal of the A M A* (Jan 23). What he finds is that the danger of infection by telephone apparatus is far less from a theoretical standpoint than the danger in crowds or from such a common article as paper currency. Earlier investigations in Germany, England, and America all gave negative results.

In this test thirty-four telephones were examined which had seen service in private residences, public booths, telephone exchanges, or had even been used by openly

tuberculous patients in sanatoriums Twenty of them had been allowed to remain uncleaned, and fourteen were given the routine cleaning of all public phones No tubercle bacilli could be detected on any of the fourteen disinfected instruments As for the others, we are assured

"No Real Danger of Infection"

In only two instances could virulent tubercle bacilli be demonstrated in guinea-pigs inoculated with dusts from the twenty uncleaned telephones, although four of these instruments had been intentionally chosen because of the repeated usage to which they had been subjected by tuberculous patients in sanatoriums In one of these cases only the bovine type bacillus could be cultured out This case can scarcely be adduced as incontestable proof of the presence of virulent tubercle bacilli on the telephone apparatus In the second case the dust used in inoculation had been removed from an instrument that had been used repeatedly and

frequently by a patient with severe open tuberculosis Only one of the four guinea-pigs used in the experiment actually became ill and in this case it was possible to culture the human type tubercle bacillus When the apparatus used by the severely tuberculous patient was cleaned, tubercle bacilli could no longer be detected in dust specimens

This is actually the first time that the presence of virulent tubercle bacilli on a telephonic apparatus has been demonstrated

This single finding ought not to be considered of any general significance, for it by no means proves that the user of public telephones runs the risk of becoming infected It should also be kept in mind that for the purpose of these examinations the layers of dirt underwent a much more thorough process of removal and collection together than would ever take place under ordinary circumstances Professor Lange concludes from his investigations that there exists no real danger of infection from the use of a telephone

LECTURES ON DIAGNOSIS AND TREATMENT OF SYPHILIS

The following schedule of lectures and hospital demonstrations in the modern methods of diagnosis and treatment of syphilis is sponsored by The New York Academy of Medicine at the request of the Commissioner of Health of New York City Attendance is open to members of the medical profession Time, 4 30 P M

"Unusual Types of Primary and Secondary Syphilis," W Bayard Long, Feb 17
 "Prenatal and Congenital Syphilis," Isadore Rosen, Feb 24

"Significance of Serologic Tests in Syphilis," A. Benson Cannon, March 3

"Epidemiology of Syphilis," C Walter Clarke, March 10

"Treatment of Syphilis," Leo Spiegel, March 17

Practical demonstration of patients, methods of diagnosis and treatment in the following clinics, to March 27

Borough of Queens Queens General Hos-

pital, Howard Fox, Mon & Thurs, 2-3
 Health Dept Clinic, Louis Chargin, Tues & Thurs, 9-10 30 Harlem Hospital, Samuel Irgang, Friday, 3-4 Lenox Hill Hospital, Leo Spiegel, Mon & Fri, a m. Mt. Sinai Hospital, Isadore Rosen, Tues & Sat, 2-3 30 St Luke's Hospital, W Bayard Long, Mon & Thurs, 1 30-3 Vanderbilt Clinic, J Gardner Hopkins, Mon 3-4 and Thurs 4-5, beginning March 1st Skin and Cancer Unit, Post-Graduate Hospital, George Miller McKee, Mon and Sat 2-4

Borough of Brooklyn Health Dept Clinic, George F Hogan, Tues and Fri, 9-12 Long Island College Hospital, Moses Silverman, Wed and Fri, 9-12 Kings County Hospital, Alfred Potter, Wed & Sat, 9-12

Borough of Queens Queens General Hospital, Rudolph Boenke, Tues & Thurs, 3-4

REVIEWS

Tissue Immunity By Reuben L. Kahn, M.S. Octavo of 707 pages, illustrated. Springfield, Charles C. Thomas, 1936. Cloth, \$7.50.

This monograph presents experimental studies relating to tissue immunity, carried out by the author and his assistants for more than five years. These were quantitative, and the ability of tissues to immunologically react has been progressively studied from the non-immune state through-out the course of reactivity to subsidence.

Tissue capability for reaction in natural, active, and passive immunity, in the young and adult, in specific tissues, have been investigated. The very complete commentary, covering the research procedures and manifested clinical phenomena, is extended into a discussion of theoretical and practical aspects. At the end of each chapter is a summary with clinical considerations which makes it easier for the reader to visualize the results so laboriously obtained. The experiments may readily be used as an out-

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W. 42nd St., N. Y. C.) postage prepaid. Order must be accompanied by remittance covering published price.

line for a laboratory course in the subject, yet the book cannot be considered as a laboratory guide or text. Despite its marked verbosity and some discursive points, such material within a single cover will lead to better understanding of the principles, should be stimulating to further research, and will be useful as a reference work to the clinician and the immunologist

IRVING M. DERBY

New and Nonofficial Remedies, 1936 Containing Descriptions of the Articles Which Stand Accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1, 1936. Duodecimo of 542 pages. Chicago, American Medical Association, 1936

In this edition a number of articles have been omitted, either because they conflict with the rules of the Council of Pharmacy and Chemistry, or because they are off the market. The grouping together of articles having a similar composition or action is continued in this edition, each group being preceded by a general discussion. As usual, the book furnishes a valuable guide in the selection of remedies

W E McCOLLOM

The Legal Aspects of Milk Control. By James A. Tobey, Dr. P. H. Octavo of 102 pages. Chicago, International Association of Milk Dealers, 1936. Cloth

This is an excellent treatise upon an extensive subject which the author has covered most admirably. The milk industry should be helped in understanding the legal aspects of milk control. Throughout the pages there is much the milk industry can learn about its responsibility in modern milk production and handling

ALEC N. THOMSON

Paget's Disease of the Nipple and Its Relation to Surface Cancers and Precancerous States in General. By Keith Inglis, M.D. Quarto of 233 pages, illustrated. New York, Oxford University Press, 1936

Dr. Inglis has contributed an excellent monograph that will find its place on the select shelf of the physician's library

An excellent historic sketch appears in the opening chapter. Frequent citations review the literature completely. A generous number of case reports, beautifully illustrated, serve to clarify the text.

The author contends that Paget's disease is neoplastic from the onset. He arrives at this conclusion after a critical survey

of inflammatory and precancerous lesions affecting the mammary ducts and the skin in general

Paget's disease in its uncomplicated form is a surface cancer, commencing at the junction of the lactiferous ducts and the epidermis, or in a lactiferous duct near its outlet. It spreads downward, by permeation of the epithelium of the duct to the acini, and outward, to the epidermis of the nipple without involving the subjacent connective tissue. Subsequently, it breaks away from the duct or acini and invades the supporting structure of the breast (scirrhous carcinoma). The Paget cell has an inherent tendency to die early, which accounts for its slow progression and the inflammatory reaction it sets up

Paget's disease must be differentiated from deep carcinoma of the breast, primary carcinoma of the nipples and ducts, eczema and dermatitis of the areola, cancer en cuirasse, Darier's disease and molluscum contagiosum

The author is convinced that no treatment other than surgery can cure Paget's disease

HARRY MANDELBAUM

Proctology. A Treatise on the Malformations, Injuries and Diseases of the Rectum, Anus and Pelvic Colon. By Frank C. Yeomans, M.D. Second edition. Octavo of 661 pages, illustrated. New York, D. Appleton-Century Company, 1936. Cloth, \$12.00

This is the second edition of an outstanding book on proctology. Numerous additions have been made to the first, which appeared in 1929

As proof that the author has attempted to include every worthwhile addition to the subject of proctology a special chapter has been added and inserted between pages 207 and 208 and numbered 207a and 207b on the important subject of pectenosis

A few of the other subjects added or revised are the technic of phenol in oil injection treatment of hemorrhoids, use of oil soluble anesthetics, radiodermatitis, lymphopathia venerea, angiomas of the colon and rectum, and subarachnoid injection of alcohol for the relief of intractable pain in advanced malignant disease.

The index, although fairly complete, does not include radiodermatitis, which is found on page 188 under pruritus ani, or lymphopathia venerea which is found under inflammatory stricture on page 361

The book is well written and illustrated, complete, authoritative, and is heartily recommended to the student, general practitioner and specialist.

CHARLES GOLDMAN

Orthopaedic Surgery By Walter Mercer, M.B. Second edition. Octavo of 906 pages, illustrated. Baltimore, William Wood & Company, 1936. Cloth, \$10.00.

This is both a textbook, and consisting of some thousand pages, is also a work of reference. The foundation of the publication is a series of lectures given at Edinburgh. The book presents an interesting angle as Mr. Mercer is a general surgeon who is addicted to orthopedics, and who has devoted much attention to the skeletal body. In producing a work of this scope he has drawn largely from the literature on the subject. However, the author includes much of his own experience which gives a personal element to the volume. This work can be suggested as a text-book for medical students. J. C. RUSHMORE

Bright's Disease and Arterial Hypertension By Willard J. Stone, M.D. Octavo of 352 pages, illustrated. Philadelphia, W. B. Saunders Company, 1936. Cloth, \$5.00.

Dr. Stone has written an interesting account of his observations on Bright's disease as seen at the Pasadena Hospital. His book will not supersede other larger works on the same subject such as Fishberg or Mosenthal but will be useful as a readable introduction to the study of kidney diseases. Especially valuable are the chapters on historical sequences and classifications, both of which will give the reader necessary perspective, although it is difficult to see why Dr. Stone found it necessary to add a new classification to the list. In this country, Volhard and Fahr's classification, especially as modified by Addison, has received such wide recognition that every attempt should be made to make it familiar to all medical students and practitioners.

It is a pleasure to note that certain recent advances are mentioned, such as the valuable fractional PSP method of estimating renal function and the use of sucrose as well as glucose in hypertonic solutions. No mention is made, however, of tetany in advanced nephritis nor of the possible therapeutic use of calcium salts in connection with twitchings, etc. Acidosis is given the chapter it deserves but in future editions we hope that Dr. Stone will mention the highly successful use of sodium bicarbonate solutions as employed by Marzullo. Arterial hypertension is covered in a comparatively brief manner, and then mostly in connection with kidney disease. There is a long, and to our mind unnecessary, chapter containing numerous autopsy abstracts.

On the whole, this is a good clinical account of Bright's disease, with especially

good historical and pathological sections, but with treatment inadequately covered.

MILTON PLOTZ

Practical Examination of Personality and Behavior Disorders Adults and Children. By Kenneth E. Appel, M.D. & Edward A. Strecker, M.D. Octavo of 219 pages. New York, The Macmillan Company, 1936. Cloth, \$2.00.

This book is essentially an outline of the technique of psychiatric examination of personality and behavior disorders in adults and children. It is divided into two sections, part one being concerned with adults, and part two with children. Outlines are presented for taking a psychiatric history, making a mental examination of the patient, as well as for physical and neurological examinations. There is an excellent summary of the complete psychiatric survey. A similar plan is followed with respect to children. In this portion of the work, outlines are presented for obtaining the history and development of the problem or behavior difficulty of a child, as well as supplementary forms for reports from the school teacher. Simple intelligence tests are suggested. There are study forms concerning habit problems in childhood which may be read by a parent to enable him to find out in what respect he has been remiss in the training of his child.

For those practitioners interested in learning a simple psychiatric technique, this book is heartily recommended.

STANLEY S. LAMM

A Textbook of Obstetrics By Edward A. Schumann, M.D. Philadelphia, W. B. Saunders Company, [c. 1936]. 780 pages, illustrated. 8vo. Cloth, \$6.50.

Edward A. Schumann, now Professor of Obstetrics at the University of Pennsylvania, has finally written his textbook. Too bad his inimitable conversational style of lecture could not be part of his text book, yet his ability and long experience as a teacher have made this a very creditable book, which is, by the way, handsomely illustrated and not too large.

Caldwell and Moloy's new classification of pelves is given more weight than in many recent textbooks, the chapter on contracted pelvis is excellent. Stander's classification of the toxemias is for the most part followed. Yet nephritic toxemia is accepted and hepatic toxemia is synonymous with acute yellow atrophy. Routine vaginal examinations are advocated, and use of pituitrin is advocated as soon as the second stage labor is complete. Anesthesia is well discussed. This book is recommended for students and general practitioners.

CHARLES A. GORDON

PATHOLOGY AND TREATMENT OF SPINAL INJURIESJOHN E SCARFF, M.D., *New York City**From the Neurological and Neurosurgical Clinic of Bellevue Hospital***I Introduction**

Considerable difference of opinion exists today regarding the methods of treating spinal injuries. On the one hand, there are those who feel that most cases of spinal injury showing signs of major cord involvement, especially spinal fluid block, should have the cord explored. On the other hand, there are those who feel that it is only in the rarest instance that operation will accomplish any good, and that in most cases, exploration only adds to the burden which the patient already must bear.

The present study is an effort to add, so far as possible, additional pathological and clinical data to that already available on the subject, and to attempt, on the basis of this data, to suggest the most rational methods of therapy. In no sense is this paper intended to be statistical. Rather, effort has been made, after a careful review of all available clinical, x-ray, and pathological material, to present certain basic principles which seem to stand out, and to illustrate these principles with brief references to typical cases. As a result of his early association with Doctors Alfred Taylor and Byron Stookey, to both of whom he is deeply indebted for instruction on this subject, and subsequently, as the result of his own experience and observation, the writer has acquired the conservative viewpoint regarding operation in case of spinal injury—namely, that it is indicated

only in the rarest instance. This paper, therefore, while intended primarily as an expression of the writer's personal view on this subject, does to a certain extent, represent the whole school of conservative thought.

The study is based essentially upon an analysis of the forty-five cases of spinal injury received upon the neurological service of Dr. Foster Kennedy at Bellevue Hospital during the past five years, with a few additional cases taken from the writer's private practice. The Bellevue Hospital cases have been observed and treated by the various members of the attending surgical staff, including Doctors Byron Stookey, Joseph E. J. King, and Dorothy Klenke, as well as the writer. Acknowledgment is also made to the office of the Chief Medical Examiner of the City of New York for valuable assistance in conducting this study, and to Dr. Lewis Stevenson for the generous cooperation of his laboratory at Bellevue Hospital.

II General Characteristics of Spinal Injuries

One of the first facts which emerges from a study of spinal injury is that there exists no constant quantitative relationship between the extent of injury to the bones of the spinal column and the extent of injury to the spinal cord. To illustrate

Fig. 1 is an x-ray of the cervical spine of a

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 28, 1936*

Fig 1 and 2 There is no quantitative relationship between the extent of injury to the spinal column and the extent of injury to the spinal cord. Fig 1 shows a normal appearing spine of a man who suffered tetraplegia following a fall. Fig 2 shows a badly fractured and dislocated cervical spine of a man who had no symptoms whatever of cord compression after a fall.

man who fell down a flight of stairs. This shows no signs of fracture, yet from the moment of his fall this man had a complete tetraplegia, paralysis of the bladder, suppression of all tendon reflexes in the legs, a sensory level at C-4, and a total block of spinal fluid.

Fig 2 is the x-ray of a cervical spine of a man who fell backward off a truck to the ground, a distance of about six feet. The x-ray shows a fracture dislocation of C-5 upon C-6 with marked displacement. Yet this man did not bother to come to the hospital until the next day, and then only because of some very slight weakness and pain over both deltoid muscles and shoulder joints.

As the study continues it becomes evident that neurological signs following any serious spinal trauma are the result of four different pathological factors acting individually or in various combinations.

These factors are

- 1 Laceration and crushing of nervous tissue by moving bony fragments at the time of original trauma
- 2 Hemorrhage into the cord

3 Edema of the cord.

4 Continuing pressure upon the cord caused by residual bony deformity.

The writer feels that the inclusive term "spinal injury" should be more generally used in referring to this type of case, rather than specific terms, such as, "fractured spine," "hematomyelia" or "dislocation"—since none of these specific conditions is apt to occur alone where there has been spinal trauma.

The role of each of the above pathological factors in the production of neurological symptoms following spinal trauma will be considered, one at a time, in the following pages, and on the basis of these considerations suggestions for therapy will be made.

III Laceration and Crushing of Nervous Tissue by Moving Bony Fragments at Time of Original Trauma

Crushing or laceration by moving fragments of bone at the time of initial trauma is, of course, the most serious of all the

four factors, since injuries of this type can never be repaired in any degree, either by natural processes or through surgical help

It would be desirable from the standpoint of prognosis, even though it would have little effect upon therapy, to determine, if possible, the extent to which the neurological symptoms in any given case were due to total section of nerves. But

this now seems impossible to do in the early states of the injury, and the writer will, therefore, not take up space in speculation upon this point

IV Hemorrhage Into the Cord (Hematomyelia)

Hemorrhage into the cord (hematomyelia) is an almost constant pathological sequel of spinal trauma. It is present, in greater or lesser degree, whenever the cord has been contused by a fractured vertebra, and is an important factor in producing the symptoms which follow.

Fig 3 Hemorrhage into the cord (hematomyelia) occurs, to some degree, in almost every spinal injury. This hemorrhage occurs almost exclusively in the central gray matter of the cord, which it destroys for a considerable distance in both directions from the site of trauma.

Fig 4 In hematomyelia the bulk of the hemorrhage is usually slight. It produces symptoms, not by pressure-effects on the passing tracts, but by interference with cells and association pathways in the central gray matter of the cord—chiefly the anterior horns. Operation accomplishes nothing in this condition.

Fig 5 Atrophy of the intrinsic muscles of the hand occurs when the anterior horn cells are destroyed by hemorrhage. This atrophy causes a typical deformity—the so-called "spinal hand."

Fig 6 The lower extremities usually recover motion and power more rapidly and completely than the upper extremities. This is the patient whose hands are shown in Fig 5

It may even occur after indirect trauma to the head or body when there are *no* signs whatever of a fractured spine, and, indeed, sometimes when there is hardly even an adequate history of trauma. For example

A seventy-six year old retired policeman rolled out of bed on the floor while asleep, falling a distance of only about two feet. He had an immediate tetraplegia, paralysis of the bladder, and loss of sensation below the level of C-3, in spite of which x-ray of his cervical spine revealed no fracture. Three weeks later, while he was beginning to show very definite improvement, this man died suddenly of a pulmonary infarct. Examination of his spinal cord at autopsy showed a recent hemorrhage into the spinal

cord, of the type to be described in the next paragraph, which had been responsible for his sudden paralysis

The *essential pathological feature* about these hemorrhages into the cord is that they occur almost exclusively *within the central gray matter*, which they dissect progressively both up and down the cord, involving only very slightly the peripheral white matter making up the longitudinal fasciculi. Fig 3 and 4 illustrate these points very clearly. It will be seen from these photographs that the gray matter is practically "*pitied*" by the hemorrhage. It will also be noted that the cross section bulk of the clot is comparatively small—too small, in fact, to exert any serious *pressure-effect* upon the longitudinal nerve fibers which pass close by *

The reason for this predilection of the hemorrhage for the gray matter in the cord is not clear unless it be that this part of the cord is relatively less dense than the peripherally placed longitudinal fasciculi, but whatever the reason for it, that pathological fact explains the clinical observation which we have made many times, namely, that, in people with spinal injuries in the cervical region, the paralyses of the legs and bladder may clear up quickly and almost completely, while that in the arms and the hands tends to improve much more slowly and much less completely. In addition there usually appears in cases of hemorrhage into the cervical cord, a marked atrophy of the muscles of the forearms and hands—such as follows destruction of the anterior horn cells in the gray matter—producing the typical deformity seen in cases of syringomyelia or central tumor of the cervical cord, the so-called "spinal hand" (Fig 5)

How shall hemorrhage into the cord be treated? In the writer's opinion, not by surgery. For by the time that the injured patient has been brought to the hospital, has been examined, x-rayed, and prepared for operation, at least one to two hours will have elapsed. By

* Specimens and photographs of the cords, loaned by courtesy of the office of the Chief Medical Examiner, of the City of New York, for this publication

March 1, 1937]

Figs 7 and 8 The spinal cord after trauma may quickly swell to almost twice its normal size, as a result of edema. The above microphotographs are cross sections of the white matter in Fig 7, a normal cord, Fig 8, a traumatized, edematous cord

this time the bleeding will most surely have stopped of its own accord since these hemorrhages when seen at postmortem are never very large. But during this interval more than enough time will have elapsed for a hemorrhage, starting, let us say, in the cervical region (which is the most common site) to have already dissected up and down the cord a considerable distance, and to have "pithed" the gray matter supplying the brachial plexus. Surgery can retrieve nothing here.

It has been urged by some that in these cases the cord should be exposed by laminectomy and attempts made to aspirate the blood within the cord by means of a needle and syringe, although it is probable that long before exposure of the cord could be made, most of the extravasated blood would have been clotted and would not pass through a needle. Under these circumstances, it is then urged that the cord should be split down the dorsal midline and the clot extracted, or allowed to extricate itself. These suggestions, however, ignore the essential pathological fact that the hemorrhage produces its chief effect on the cord by invading and disrupting and partially destroying the delicate individual cells and association pathways within the gray matter, in exactly the same way that the spring flood of a

Fig 9 A spinal cord—edematous and swollen as a result of trauma—will fill the dural sac and exert great expanding pressure in all directions against its walls. Incision of the dura in such cases is likely to cause instant herniation of the cord with permanent loss of substance.

river, swollen and jammed with ice, invades and destroys the individual structures and communications of a valley down which it sweeps. Passing a knife blade through a spinal cord in this state will not repair the damage and would probably add to it.

What, then, can one accomplish for

these patients? The key to the answer lies in the hope—which is very often a fact—that the destruction of tissues is not as great as would appear at first, in the same way that after a flooded river subsides, it is found that many structures and lines of communication, which were

in this paper will serve to illustrate this point

P C, a forty-one year old laborer who fell down a flight of stairs, was brought to the hospital immediately afterward with a complete tetraplegia, loss of all sensation below the level C-4, paralysis of the bladder,

Fig 10 The diameter of the spinal cord is normally only about one-half the diameter of the neural canal—so that a fifty per cent encroachment upon the bony canal may take place before compression of the cord begins (The figures here shown have been traced directly from cross sections of a frozen cadaver¹)

at first thought to be hopelessly destroyed, can be salvaged, and with effort made to function again to some extent. In a relatively large number of patients this is true. The return of function is usually not complete, although it may be nearly so. This is particularly true of the legs, while the hands, for reasons explained above, lag behind. The first case cited

abolition of tendon reflexes in the lower extremities, and a total spinal block. His x-rays showed no fracture (Fig 1). After about ten days of rest in bed he was able to flex both knees and thighs but was unable to move his toes and ankles, but was still unable to move his hands. A month after his accident he could move both legs quite well. The hands were still paralyzed, however, and there was appearing some atrophy

Three months after the accident he had regained some movement in his wrists and fingers in spite of which the atrophy appeared more marked than at previous examination. Eight months after the accident he is out of bed all day with fairly good use of his legs (Fig 6). Although he is now

by pressure applied at periodic intervals over the bladder (Crede). If the urine is already infected when the patient is first seen, free drainage is of course, necessary.

3 *Physiotherapy* during period before return of spontaneous movement—passive motion, massage, and heat—to maintain circu-

Fig 11 and 12 Extreme deformities of the cervical spine, such as those here shown frequently occur without producing any serious symptoms of cord compression. (See a similar case represented in Fig 2)

able to move his wrists and fingers freely, the atrophy and deformity, typical of the so-called "spinal hand" is present (Fig 5).

The important points in the treatment of hematomyelia are these:

1 *Prevention of bed sores*. This is accomplished by the use of air mattresses and meticulous nursing care.

2 *Prevention of urinary infection*. This is best accomplished by the excellent method of "tidal drainage" recently described by Munro.¹ Repeated catheterization and the use of the ordinary retention catheter are to be avoided, whenever possible, in all cases not previously infected, since they invariably result in cystitis and other undesirable changes in the bladder. Establishment of an automatic, overflow bladder in the absence of infection is usually preferable to catheterization. Emptying can be aided materially

by pressure applied at periodic intervals over the bladder (Crede). If the urine is already infected when the patient is first seen, free drainage is of course, necessary.

4 *Systematic exercises* after spontaneous movement has appeared. These exercises should be graded according to function and must occupy the greater part of the patient's waking day.

The end results of conservative treatment for hemorrhage into the spinal cord (hematomyelia), if these rules be strictly followed, are very gratifying. In our series of cases, out of twenty cases of total tetraplegia, presumably due to hematomyelia, ten died within a period of a few hours to a few days, largely with pneumonia. Of the ten cases surviving the initial period of trauma, eight showed a very large return of function, approaching normal in the legs, but less in the hands. Two patients showed no improvement

V Edema of the Cord

Edema of the cord occurs in every spinal injury which is severe enough to produce neurological symptoms. In the *acute* initial stages immediately following the accident, it is a very important factor in the production of symptoms. It is the most frequent and usually the most important cause of manometric block in the spinal fluid during the first forty-eight hours following trauma, a point not sufficiently appreciated. It constitutes a great threat to the life of the patient when the spinal injury occurs in the upper cervical region. Yet it is a subject to which very little attention has been directed.

From the *pathological* standpoint the important fact is that *the spinal cord is capable of quickly swelling to about twice*

Fig 13 Comminuted (depressed) fractures of spinous processes and laminae constitute almost the only fractures where laminectomy is unquestionably indicated

its normal size within a very few minutes after being traumatized. In this state it completely fills the dural sac and distends it under considerable pressure. The microscopic appearance of such a distended cord is contrasted with that of a normal cord in Fig 7 and 8.

From the *clinical* standpoint the important point to be determined is whether, in the presence of such a swollen edematous cord, the dura should be opened widely as a decompressive measure, or should be left closed. On this point there exist two widely divergent opinions. The writer feels, however, that both reason and experience council the conservative course. Theoretically, with the cord so edematous and tense, there would be great tendency

to sudden herniation and spontaneous rupture if any opening, whatever, were made in the limiting membrane of the cord—represented here by the dura (Fig 9).

That this *does* actually occur when the dura is opened under such circumstances was pointed out a good many years ago by Taylor,¹ of this city, who reported at that time two cases in his own experience in which this had happened. In each instance the patient, although temporarily paralyzed at the time he was taken to the operating room for laminectomy, was comfortable, and, excepting for the paralysis, in good general condition. In each instance when the dura was opened there was an instantaneous and violent extrusion of the cord through the incision. In one case fully two inches of the cord was thus blown out within a few seconds. In each instance the two patients immediately developed hyperthermia and shortly afterwards died. It has been this writer's fortune while an onlooker in two different cases to observe the same phenomenon. Two other quite similar cases have been reported to the writer in detail by another physician.² Our own records at Bellevue Hospital contain another somewhat similar case.

It would seem that we are considerably more advanced in our understanding and treatment of *cerebral* edema than we are in our understanding and treatment of *spinal* edema. We have learned, for example, that the great majority of *cerebral* concussions will do better if treated conservatively than if decompressed surgically. Instead of operating we now combat *cerebral* edema with physiological rest and *dehydrating* agents. The same principles of therapy, the writer feels, should apply to the treatment of spinal edema. He, therefore, advises against surgical decompression and recommends the intravenous injection of fifty per cent glucose (50–75 cc) every three or six hours during the first two or three days.

VI Continuing Pressure Upon the Cord Caused by Residual Bony Deformity

In almost all fractures of the spine there remains some degree of bony deformity, which, if gross enough, may exert continued pressure upon the cord,

and be in part responsible for neurological symptoms

The importance of this residual bony deformity in producing or prolonging neurological symptoms is, however, in the opinion of this writer, far less than is usually assigned to it. This opinion is based partly upon the anatomical fact that the diameter of the spinal cord is normally only about one-half (in places one-third) of the diameter of the bony canal,⁸ so that approximately a fifty per cent encroachment upon the lumen of the canal is necessary before serious compression of the cord begins (Fig 10)

Even after this degree of encroachment has been reached the cord has considerable capacity for accommodating itself to a change in shape. This has been clinically demonstrated many times in cases of Pott's disease of the spine where extreme deformity frequently occurs without any neurological signs. Even in our series of *acute* spinal injuries there is ample proof that considerable encroachment upon the lumen of the bony canal may take place without causing paralysis. To illustrate

Fig 11 shows a pathological fracture of the cervical spine which occurred suddenly. There exists a bizarre distortion of the spine and there must be almost total obliteration of the bony canal at several points. In spite of this, however, the patient walked into the hospital complaining only of pain in the neck.

Fig 12 is an x-ray of the cervical spine of a man who fell down a flight of stairs with a one hundred pound sack of coal resting upon his neck and shoulders. There is an extreme anterior displacement of C-1 upon C-2, amounting to almost the full anterior-posterior diameter of the body of the second vertebra. Yet this man's chief complaint was slight pain in the back of the neck.

Fig 2 (discussed earlier in the paper in another connection) also shows an extreme forward dislocation of C-5 upon C-6, brought on acutely by a fall. There is present about a sixty per cent overriding of the vertebral bodies. Yet when examined some hours after the accident, this patient gave no serious subjective symptoms of cord compression.

Correction of deformity is generally desirable, however, in all cases of fractured spine regardless of the degree of cord compression resulting from the de-

formity, for the reason that any deformity, if uncorrected, tends to become progressively worse and so may eventually produce greater symptoms.

Deformities tend to follow rather fixed patterns, determined more or less by the site of the injury and the initial force of the trauma. A resume of the typical spinal fractures with their resultant deformities is given below, together with brief discussion of the *rationale* and methods for correcting each type of deformity.

Satisfactory reduction is possible in almost all instances by "closed" nonoperative procedures. In the opinion of the writer, correction of the deformity by operative measures is indicated in only the rarest instances. In most cases, it is his opinion that surgery is not only ineffective, but definitely harmful.

After the correction of the bony deformity the treatment of a fractured spine is the same as the treatment of hematomyelia or edema of the cord, as outlined in the preceding parts of this paper.

1 Commuted fracture of the lamina (Fig 13) This type of fracture is exceedingly rare. It is produced by the direct force of a heavy instrument directly against the spines of the vertebra. This is one of the very few fractures of the spine where the writer believes that open operation is definitely indicated. Laminectomy should be performed as soon as possible and all bony fragments removed.

2 Fracture-dislocation of the cervical spine A very special function of the cervical spine is mobility. The head must not only move forward and backward, to right and to left, but also must rotate around the long axis of the body, and for this reason all facets along the cervical vertebrae are shallow, and all articulations are extremely loose. These anatomical and functional facts predispose the typical "fracture-dislocation" of the cervical spine, which is by all odds the most common fracture encountered. In these cases a sudden throwing of the head forward puts extreme stress upon the relatively weak articular processes of the spine, one or both of which at any particular level may be broken off. When the articular process on one side only is broken, a slight

forward rotation of the upper part of the spine takes place, when the articular processes on both sides of the vertebra are broken there is a general slipping forward of that part of the cervical spine about the level of the fractures (Fig 14 and 15)

Reduction of fracture-dislocations of

Several methods of applying this principle have been devised. Dr Alfred Taylor,¹ many years ago, advocated the reduction of deformity by "halter-traction" and immediate immobilization in a plaster cast extending from beneath the chin and occiput down over the shoulders and chest (Fig 16-A). We have employed

Fig 14 A typical "fracture-dislocation" of the cervical spine results from a breaking off of the articular processes on one or both sides of a given vertebra. This permits either a forward rotation (if the fracture is unilateral), or a complete forward slipping of the entire upper part of the cervical spine (if the fracture is bilateral)

the cervical spine are best accomplished, in the writer's opinion, by nonoperative measures, based upon the well-acknowledged fact that sustained traction upon the head along the longitudinal axis of the spine will easily and quickly overcome the spasm of the muscles of the neck, permitting the falsely locked bony parts to be disengaged, and allowing almost perfect realignment (Fig 17)

this procedure at Bellevue Hospital many times with most satisfactory results. A brief account of a fracture-dislocation of the cervical spine treated by the Taylor method is here given

A boy of nineteen years was riding in the back of a truck which collided with another. He suffered an immediate quadriplegia, with retention of urine. The first x-ray taken of the spine failed to show any

Fig 15 Fracture-dislocations of the cervical spine as above described are by all odds the most frequent spinal fractures. These usually involve the fifth or sixth cervical vertebrae—as shown in these x-rays

fracture (Fig 17-A). By pulling the shoulders down, however, exposure of C-6 and C-7 was obtained, which revealed a typical anterior "fracture-dislocation" of C-6 upon C-7 (Fig 17-B). "Halter-traction" relaxed the muscle spasm and allowed normal realignment of the spine (Fig 17-C). A plaster cast was then applied to the neck and body (Fig 17-D). When discharged from the hospital some six months later, without cast or brace, the boy was able to walk alone and had about 70 per cent return of function in both upper and lower extremities.

Another ingenious method for treating these fractures has been proposed by Crutchfield,⁴ who has devised a set of "tongs"—resembling ice-tongs—which he applies directly to the bones of the skull and by means of which he is able to exert true skeletal traction in reducing the muscle spasm in the neck (Fig 16-B). The writer's experience with this method

is too limited and brief to justify him in making a comparison between this method and the earlier method of Taylor. It is true that the "tongs" are much easier

Fig 16 Fracture-dislocations of the cervical spine are best reduced by nonoperative measures. Three satisfactory methods of reduction are here pictured (A) Taylor method, (B) Method of Crutchfield*, (C) Stookey method

to apply than is the plaster cast, and are certainly more comfortable for the patient, but whether the lack of fixation is "desirable" or "safe" has not been settled to the writer's complete satisfaction. In any event, however, Crutchfield has made a distinct contribution to our ideas on this subject.

A third method for reducing cervical

fractures was evolved by Stookey⁵ at Bellevue Hospital several years ago, in which work the writer had the pleasure of assisting him. The essential feature of this method is an air mattress, at the head-end of which a deep "trough" is made by means of a broad band of adhesive tape which is fastened to the upper surface of the air mattress, carried over the end of the mattress, pulled strongly downward, and fastened to the frame of the bed (Fig 16-C). The head and neck rest in this "trough" in a position of acute hyperextension, maintained by the weight of the head itself. Although quite simple, this method has proven very effective, especially in the simpler fractures.

Laminectomy not only is unnecessary in these cases, as pointed out in the above paragraphs—but may even be dangerous. By further weakening the ligamentous and muscular support of the bony spine, laminectomy greatly increases false mobility, with added danger to the cord.¹⁴

3 Compression fractures Although compression fractures may occur at any level of the spine, by far the greatest number affect the twelfth thoracic or the first lumbar vertebrae. There is an anatomical reason for this. In the lumbar spine, in contrast to the cervical spine, great mobility is undesirable, and strength to support the great weight of the body is the prime objective. As a result, articular processes are strong and heavy, and the articular facets are deeply placed, so that fracture-dislocation, such as takes place in the cervical spine, is practically impossible (Fig 18-A and B). In these vertebrae, motion is limited to a slight forward and backward rocking of one vertebra upon another. Attached to these limited joints from above is the rigid and very heavy "thoracic cage." Any sudden force which throws this heavy structure violently forward tends to force the lumbar articulations past their normal limits of motion. In the neck this would result in a fracture of the light articular processes—and "dislocation", but in the lumbar region, because of these strong and deeply placed articulations, fracture-dislocation rarely takes place. Instead, the articulating facets act as fulcrum in such a way as to bring the bodies of the vertebrae closer together with considerable force. Under

* Tongs made by Pilling, Philadelphia

Fig 17 Reduction of a typical fracture-dislocation of the cervical spine by the method of Taylor, (See text and Fig 16-A), is here recorded in x-rays. The fracture was hidden by the patient's shoulders when the first x-rays were taken (A), but was revealed when the shoulders were pulled downward (B). "Halter-traction" upon the head easily relaxed the spasm of the muscles of the neck and permitted good realignment of the vertebral bodies (C), which was maintained by application of a plaster cast (D). The tetraplegia of this patient rapidly improved after reduction of deformity.

Fig 18 In the lumbar spine the articular facets are so broad and deep, and the articular processes so strong (A & B), that fracture-dislocation, as found in the cervical spine, almost never occur in this region. Instead, in the lumbar region compression fractures of the bodies of the vertebrae (C) are the rule

this compression force the internal structures of the bodies give way and the so-called "compression fracture" results (Fig 18-C and 19)

The twelfth thoracic and the first lumbar vertebrae succumb most frequently, they lack on the one hand, the support given to most of the thoracic spine by the long overlapping spinous processes, and by the ribs, while on the other hand, they have not yet acquired the great size and

strength of the lower lumbar vertebrae

The most rational and effective method for reducing this type of deformity is *hyperextension* by mechanical measures. (Fig 20) Actual bony encroachment of the neural canal in these cases is practically negligible, (verified by exploratory operation in two of our cases),* and the symptoms which accompany them

* Also verified at operation in one case by Dr Taylor¹

Fig 19 Compression fractures most frequently involve the bodies of the 12th thoracic or the first lumbar vertebrae

are due largely to hemorrhage within the cord, edema, internal disarrangement within the cord resulting from sudden angulation, and changes of length. Laminectomy could do nothing to relieve injuries of this type, nor could it possibly repair the crushing damage done to the body of the vertebra. On the other hand, laminectomy, with removal of the vertebral spines and the laminae, would, to a very considerable degree, reduce the effectiveness of any mechanical measures taken to correct the deformity by means of hyperextension.

Following correction of the bony deformity by hyperextension, the treatment then becomes the same as that for hematomyelia, and edema of the cord, which has been discussed in detail in the preceding sections of this paper.

4 Fracture-dislocations of the thoracic spine The thoracic vertebrae are so strongly reinforced by their overlapping dorsal spines, and by the ribs (Fig 21 A and C) that they are seldom fractured. The very occasional compression fracture of a vertebral body which does occur, is, of course, treated in the same manner as a compression fracture of the lumbar region. Whenever trauma occurs which is great enough to produce a "fracture-dislocation" of the thoracic spine, it is usually trauma of such violent nature that it plays havoc with the spine and associated structures—fracturing, comminuting, and badly dislocated two or three vertebrae, as well as adjacent ribs (Fig 21-B and 22). This is the type of injury which occurs when a patient falls from a high building and lands upon a fire-escape, or which occurs in violent automobile accidents where passengers are thrown out against trees or posts.

The spinal cord in such cases is usually completely severed, leaving total flaccid paralysis, urinary retention, and abolished reflexes. All three cases of fracture-dislocation of the thoracic spine in our series were of this type.

Unfortunately, there is little to be done excepting to make the patient comfortable

VII Delayed Secondary Changes in Spine Following Trauma

In some cases degenerative changes in the bones of the spine are not present immediately after injury or during first hospitalization, but subsequently appear, weeks or months later (Fig 23). The

Fig 20 Hyperextension of the spine is the most rational and effective means of correcting the bony deformity resulting from a compression fracture of the body of a spinal vertebrae.

nature of these changes, or the mechanism involved, is not clear. They may be upon the basis of destructive arthritis, or upon the basis of thrombosis of nutrient arteries going to the bones.

Mention of this fact is made, however, because of the possibility of legal complications arising out of such late changes, against which proper precautions should always be taken.

Summary

1 Analytical review of cases of spinal

Fig 21 The thoracic spine is strongly reinforced by the over-lapping spinous processes of the vertebrae and also by the ribs, (A) and (C). Any force strong enough to cause a fracture-dislocation of this part of the spine usually produces extreme, severe, comminuted fractures of several vertebrae and their corresponding ribs (B)

injury received during a period of five years on the neurological service at Bellevue Hospital establishes the fact that there is no quantitative relationship between the extent of injury to the bony spine and the extent of injury to the spinal cord

2 The neurological symptoms following spinal trauma are found to be due to four factors

a Laceration and crushing of nervous tissue by moving bony fragments of bone at the time of original trauma

b Hemorrhage into the cord

c Edema of the cord

d Continuing pressure upon the cord caused by residual bony deformity

For this reason the writer suggests the more common use of the term "spinal injury" rather than such limiting terms as "spinal fracture," "hematomyelia," etc

3 A clinical, x-ray, and pathological correlation of these four factors has been made in this paper, with brief citation of case records to illustrate principal points

4 The *rationale* and methods for treating each of these four factors is presented

5 Nonoperative methods of treatment yield good results. Surgery, in the writer's opinion, is strongly contraindicated except in the rarest instances

Fig 22 Fracture-dislocations of the thoracic spine occur only after the most severe trauma, as when a person falls from a great height or is thrown from a rapidly moving car against a tree. There is little hope for functional recovery in these cases because the cord is usually completely severed.

Fig 23 Late degenerative changes in the bones of the spine sometimes appear weeks after the trauma occurred. A typical instance is here shown. (A) shows a cervical spine of a man brought to the hospital with a slight trauma to the head, but without any signs referable to the spine. Three months later X-rays of the cervical spine, taken in the course of a routine follow-up, revealed extreme degenerative changes in the bony vertebrae with marked fracture-dislocation at C-6. This type of change offers medicolegal complications.

(X-rays shown through the courtesy of Doctor C. H. Pohlmann of Middletown.)

FOUR O'CLOCK FATIGUE

It is generally conceded that the morning is the time most conducive to good work whether it be physical or mental. At noon we pause—and should relax—while we stow away a little provender to replace the fuel that has been utilized in the forenoon's activity.

After getting under way again, it is the customary experience to find a tendency to earlier slowing down of work than before. Along about 4 o'clock there is a perceptible lagging of effort. In the hot Spanish-speaking countries of the western

hemisphere, a *siesta* is observed which affords recuperation through an afternoon nap.

The four o'clock coffee habit of the Scandinavians and the Englishmen's afternoon tea are also excellent means of coping with this afternoon fatigue. In this country there is a tendency to popularize the cocktail hour, which, however, is far less satisfactory. Something should be done, however, to promote a properly observed 4 o'clock pause—*The Journal-Lancet*.

SILICOSIS IN MODERN FOUNDRIES

Study of the Incidence

JOHN F KELLEY, M D and ROBERT C HALL, M D, *Utica*

On September 1, 1935 silicosis was included as a hazard compensable under the State of New York Workmen's Compensation Law for foundry workers. Prior to that time, in a space of a few years, a number of law suits had appeared on the court calendars against industries who have a dust hazard, but were not included under compensation. Silica dust as the aggravating factor in the production of certain types of pneumoconiosis has long been recognized, and the association of tuberculosis and silicosis in workers exposed to such dust for long periods is too well-known to warrant detailed discussion. The purpose of this paper is to point out some aspects of the problem as determined in a group of workers in three foundries in Utica.

These examinations and studies were performed at the request of the foundry owners following the incorporation of silicosis as a compensable disease. Up to this time very little was known of silicosis in the foundry industry. No group of examinations had been made on which to base the incidence of silicosis occurring in foundry workers. In fact, so little was known about it that a state of uncertainty bordering on hysteria was manifested both by the insurance carriers and the foundry owners. During this period of unrest, the insurance companies set a premium which was prohibitive for employers to pay on employees without an examination. Their only recourse was to have these examinations made with the understanding between themselves and the insurance carriers that any men suffering from silicosis would not be employed. This opened up a rather serious problem, as it left the employers liable to suit by the discharged workmen, especially if they had been in their employ a number of years. Up to the present time, this problem has not been solved satisfactorily.

Method of Examination

The method of examination, as agreed by carriers, employer, and ourselves, was decided that all men were to receive a physical and an x-ray examination, these to be independent of each other, and the findings to be reported to the employer, and retained by the insurance carriers, who again examined the plates and the physical examination forms. A blank, general in character with a few details pertaining to the chest, was composed for the examination. The points stressed in the examination were chest expansion, auscultation, cough, dyspnea, and weight. In making the x-ray examinations, 100 milliampere technic was employed, varying the voltage to the thickness of the chest and keeping the time between one-tenth and one-twentieth of a second, single films were made at a distance of six feet. The cases were classified as first, second, and third degree stages of silicosis, and there was another large group of cases with an exaggerated pulmonary pattern or increased perilymphatic fibrosis which we classified as "dusty lungs." These men had been working many years in the foundries, but still had none of the nodulation of silicosis. The problem was to determine the incidence of silicosis, tuberculosis, and other pulmonary diseases in these workers. The examination was divided into two parts—history and physical examination. In the history, previous employment in foundries or other dusty occupations were carefully noted. Generally, complete denial was made of any previous respiratory disease, so that outside of the occupational history the past history was more or less useless. On physical examination, all authors on the subject¹ of silicosis and pneumoconiosis give as the cardinal signs of silicosis, loss of weight, dyspnea, and limitation of expansion of

the chest. In this series all these signs were more or less variable and inconsistent, and in none of the cases, which had silicosis, did we find loss of weight. Dyspnea was present in only one case. Limitation of expansion was fairly constant, being found in three of the four frank cases of silicosis. It must be borne in mind, however, that in this series of examination, no second or third degree silicosis was found. One physical sign, which was found in practically ninety per cent of the cases showing perilymphatic fibrosis or nodulation in the x-rays, was coarse breath sounds both anteriorly and posteriorly in the lungs. This could only be described as wind or air blowing through a rather large pipe.

A total of 403 examinations were made in the three foundries. Two of the foundries employed between 150 and 200 men in each, while the third employed about fifty men. A marked difference in these three places was noted in the occurrence of the disease. In the small foundry, two of the four cases of silicosis were found, and a large percentage of the cases with perilymphatic fibrosis, which we termed "dusty lung." In both of the large foundries every effort had been made to overcome the dust hazards in the past ten years. All the latest precautionary devices for the removal of dust have been utilized. In the small foundry no unusual precautions have been taken to overcome the dust hazard. In foundry workers, outside the moulders and shaker-outs, very few of the men were exposed to any appreciable concentration of dust.

Silicate Content in Sand

The percentage of silicate in their moulding sand, which was determined by one large foundry, was 79.6 per cent. No record was obtained from the other plants as to the silicate content of their sand, but it is understood that the normal silicate content in sand is approximately eighty per cent.

On analyzing Table I, it will be noted that a total of 403 cases were examined. Of that number 363 cases were negative, a percentage of 90.07. There were four cases of first degree silicosis, a percentage of .99. One case of silicosis with tuber-

culosis, making a percentage of .25, or a total percentage of 1.24 cases of silicosis. Of those classed as "dusty lung" there were 30 cases, giving a percentage of 7.45. It is evident that the percentage of silicotics in this series of cases is very low, with no cases above first degree.

In analyzing Table II, it will be noted that in Plant I, there are fifty employees. Out of that fifty there were two cases of silicosis. In this plant, which was a very small place, none of the modern aids for

TABLE I

	<i>No</i>	<i>Percentage</i>

T.B. and Silicosis	1	.25
T.B.	4	.99
T.B. and Dusty Lung	1	.25
<i>Total</i>	<i>403</i>	

eliminating dust had been utilized. In Plants II and III, which are large modern plants in which all the present accepted methods for the removal of dust had been installed, there were only two cases of first degree silicosis out of a total of 353 cases examined.

In analyzing Table III, it will be noted that the moulders, who are by far the largest group, had three cases of silicosis, the shaker-outs, which are a rather small group, had one case. It is in these two groups that most of the exposure to dust occurs in the foundry.

On Table IV, insofar as silicosis is concerned, in analyzing it will be noted that the ages run from forty-four to sixty, the average age being fifty-two. As to the number of years in which these cases worked in the foundry, a man with slight nodulation aged fifty-two, worked for five years as a shaker-out, in which there is always a large concentration of silicate dust present. The other men, all moulders, worked from seventeen to forty-seven years, the average being thirty years, and none of these cases had more than a first degree silicosis. The other portions of Table IV are self-explanatory.

Discussion

Following these examinations, as you will note from the tables we were all

rather agreeably surprised at the low incidence of silicosis in these three foundries. It is our belief that because of the small number in this series, and due to the fact that the two large foundries had all the latest devices for the prevention of dust concentration, that this percentage is very low. On comparing them with the results found by Pope and Zacks,² who examined ten foundries in the state of Massachusetts, our percentage of silicosis cases is much lower. They found 88 per cent uncomplicated silicosis and 26 per cent silicosis and tuberculosis—for a total percentage of 114 per cent in two thousand examinations. It was also rather forcibly brought to our attention, as it happened so many times, that certain statements regarding symptoms start in text books and are carried on traditionally through other text books, such as loss of weight,

dyspnea, and limitation of respiration are symptoms of the late stage of silicosis, and are not present in the early silicotics. From physical examination alone a diagnosis of silicosis in any stage cannot be made, although in the third stage it is possible to be suspicious of its presence. Although a diagnosis may be made of silicosis on an x-ray alone, we believe a combination of x-ray and examination is the only safe method.

Conclusion

Instances of silicosis in this series is low as compared to a similar study made in Massachusetts. The occurrence of silicosis in foundry workers, as shown by this series of examinations, and those made in Massachusetts, is relatively low compared to other dusty industries, and is not as

great a hazard as was felt both by the employers and insurance carriers at the time this condition was incorporated in the compensation law. After reviewing the ages of these different workers, the number of years they had worked in the industry, and their job, it is our feeling that

First Men working as shaker-outs develop the disease much sooner than moulders.

Second In foundry workers in general the disease is developing over a long period of time, and never reaches the severity of other dusty industries.

Third As a hazard with the present modern appliances for the removal of dust, silicosis should not be considered a greater hazard than any traumatic injury occurring in the same industry.

There appears to be a relationship between concentration of dust and the time of exposure. The cutting down on the concentration hinders the development of silicosis, and workers in the foundry have to be exposed to the dust for a long period

of time before development of the disease. A close study of the statistics also discloses the very valuable information that all employees exposed under the same conditions do not develop silicosis. This may be attributed to a natural or an acquired resistance.

What to do with the men who were found to be silicotics is still an unsolved problem. From their examination, and the years they worked in the foundry, we believe they should be put back on the jobs which have the lowest dust hazard. Those who have tuberculosis, of course, should be placed in sanitarium, and in the individual cases found in these examinations, that was done.

Physical signs, except in late stages, are noticeable by their absence.

USE OF RADIUM IN STERILIZATION

Sterilization by irradiation when properly administered by a trained therapist, is effective and at the same time produces "no untoward effects," Dr. Ira Kaplan, director of the division of cancer in the Department of Hospitals, said in a symposium on sterilization at the New York Academy of Medicine on Nov. 24.

The symposium was held as a regular meeting of the section of obstetrics and gynecology of the academy, sterilization being discussed from the viewpoints of eugenics, obstetrics, therapy and other approaches. Dr. Arthur Mitchell Reich, who presided, emphasized that the material presented by the speakers was "purely informative" and that it did not "imply an indorsement of this body of these measures."

Irradiation sickness might occasionally occur from this type of sterilization, Dr. Kaplan said, but this condition was relieved with cessation of the treatment.

"When radium is employed," Dr. Kaplan said, "proper surgical precautions are essential to prevent infection or perforation. Radium therapy must not be administered

in the presence of adnexal infection.

"In young women sterilization may be permanent instead of temporary, and in some cases sterilization by irradiation may not prove effective, requiring surgical procedures. To obtain effective results, it is essential that irradiation sterilization be carried out only by those properly prepared by training and experience in the employment of X-ray and radium therapy."

Dr. Kaplan added that the effectiveness of irradiation sterilization was equal to that of surgery "without the latter's associated mortality and morbidity."

Dr. Benjamin P. Watson, former president of the American Gynecological Society, reported that in the last five years 172 women had been sterilized at the Sloane House for Women. In each case, he said, sterilization was carried out in conjunction with some other operative procedure.

"Sterilization done along with abdominal hysterotomy in early pregnancy was performed in those patients having complications which rendered any further pregnancy hazardous," Dr. Watson said.

THORACOSCOPY AND INTRAPLEURAL PNEUMOLYSIS

Report of Fifty Cases

HARVEY B. POWERS, M D, *Lake Kashaqua*

There has been a marked tendency in recent years to broaden the indications of the use of artificial pneumothorax in the treatment of pulmonary tuberculosis. The presence of cavity, however, continues to be the most universal indication. Should pneumothorax fail to close the cavity within a reasonable time, continuance is not only useless, but the possibility of complications is enhanced. Inability to close cavity in a major percentage of cases is due to the presence of adhesions, and it is in these cases that one is tempted to use high pressure pneumothorax with the attendant danger of tearing adhesions, perforation of the lung, and empyema.

Here, intrapleural pneumolysis is desirable and is indicated as soon as it is demonstrated that the cavity or cavities will not close under ordinary pressures. We feel also that pneumolysis should be performed in instances where an adhesion is directly over a large cavity even though the cavity be closed and the sputum negative for tubercle bacillus. In several of our cases, in which pneumothorax was induced prior to the use of cautery, upon re-expansion of the lung three to five years later, the cavity was found still open.

The operation is not without risk and should be attempted only by a surgeon with skill and experience. The choice of method, whether electrocautery or surgical diathermy, depends upon the preference of the operator and the type of adhesion. Many adhesions appear in the x-ray film to be so situated as to render cautery impossible, but thoracoscopy has shown that many seemingly hopeless ones can be cauterized. For this reason, all doubtful cases should have a thoracoscopic examination.

The continued use of any one surgical procedure should be determined by its success or failure and, with this in mind, we have reviewed all cases in which cautery was used at Stony Wold Sanatorium. From January 1927 to July 1935, we at-

tempted artificial pneumothorax on three hundred cases. Of this number, thirty-six resulted in failure because of obliterative pleuritis. Of the remaining 264, 132 presented adhesions of a varying degree and of these, sixty-two (47%) or 23.4 per cent of the total did not interfere with a satisfactory collapse. Fifty or 37.9 per cent of the 132 presenting adhesions were thought suitable for cautery, but after thoracoscopy, two were impossible. The operations were performed at Stony Wold Sanatorium by Dr. E. S. Welles of Saranac Lake. Electrocautery was used in all cases.

Sex. All patients were females.

Age. The youngest patient was seventeen and the oldest forty-seven. The average was twenty-four years.

Stage. Nine or nineteen per cent of the forty-eight cases were classed as Stage II or moderately advanced. Thirty-nine or eighty-one per cent were Stage III or far advanced. There were two cases of bilateral pneumothorax.

Interval. The interval between the beginning of pneumothorax treatments and of pneumolysis averaged four and a half months, the longest eleven months and the shortest six weeks. There is no rule as to the length of time artificial pneumothorax should be continued before pneumolysis is attempted, but it should be done when it is shown that the cavity cannot be collapsed without the use of undue high pressures.

Results. Pneumolyses have been considered technical successes if all interfering adhesions were cut and clinical successes only if the sputum became negative. Of the forty-eight cases, forty-three or eighty-nine per cent were termed technical successes and forty-one or eighty-five per cent clinical successes. The seven cases continuing with positive sputum were unsuccessful for the following reasons:

There was one case of pleurobronchial fistula following cautery with death occurring from extensive disease in the opposite lung. In two cases, a positive sputum was obtained, but it was our opinion that it came from lesions in

the opposite lung. One technically successful pneumolysis, in which all adhesions were severed, failed to collapse the cavity. In another technically successful case, in which the patient had a very satisfactory collapse, it was necessary to prematurely re-expand the lung because of extensive progressive disease on the opposite side. Two other patients, in spite of cautery of most of the adhesions, never obtained an effective collapse.

Postoperative. Fifty-one per cent of the patients were without fever, forty-nine per cent had elevations of temperature of 99.2° to 104.0°F. In only one, the latter, did fever continue for any prolonged period. Post-operative shock occurred in one case. Four showed dyspnea and one a marked increase in cough. No bleeding from the cut adhesions that was not readily controlled was encountered. Great care was exercised before the patient left the table to see that there were no oozing or bleeding areas.

Fluid of the transitory type appeared in twenty-two or forty-six per cent of all cases and persistent fluid (that requiring aspiration one or more times) in thirteen or twenty-seven per cent. None of these became purulent.

Mediastinal herniation of varying degree occurred in fifteen cases. Subcutaneous emphysema occurred in fifty per cent of the cases, but was not serious in any of them.

More serious sequelae. Tuberculous empyema followed cautery in three cases. Two cases developed purulent fluid at a date sometime after operation and one as an immediate result following a pleurobronchial fistula. This case terminated fatally because of rapidly progressive disease in the opposite lung. In the other two, the pus was apparently absorbed. Empyema of staphylococcal origin was encountered in one instance. This was treated successfully by the closed method, by aspirating, washing with saline solution and with 1:4000 gentian violet. Pleurobronchial fistula occurred in

two cases. In one previously mentioned, a tuberculous empyema resulted. In the second, a bilateral pneumothorax case, there was no empyema. However, dyspnea was so marked that the opposite lung had to be re-expanded. The fistula subsequently closed. The untoward result in this case was the re-expansion of the opposite lung. This lung, unfortunately, became adherent and subsequent attempts produced only partial collapse and the cavity was still open. Rapid re-expansion within twelve hours following cautery occurred in one of the cases early in the series. Since then, it has been our custom to examine our patients with the fluoroscope when marked subcutaneous emphysema occurs or within twenty-four hours of the cautery. No similar complication has resulted since this practice was instituted.

Cutler,¹ in his series of cases, found pneumolysis indicated in seventeen per cent, Matson² in seventeen per cent and at Stony Wold eighteen per cent. Matson reports sixty-five per cent successes, Welles,³ in his series of cases outside of Stony Wold, eighty-five per cent and at Stony Wold eighty-five per cent.

Comment

From an analysis of the above cases, we believe that intrapleural pneumolysis is a valuable adjunct to the use of artificial pneumothorax. This is in spite of the cases of empyema. In all three, thoracoplasty would not have been possible because of bilateral disease.

A MORAL TO JUST A LITTLE SAMPLE

An innocent little sample was left on the desk of my friend Doctor. The sample was a medical one left by a leading pharmaceutical house—for cough.

A patient came in, the Doctor was very busy, he had no time to examine and prescribe for this coughing patient, so handed the sample to the patient and dismissed her.

The sample did the work and so the patient passed the label to her neighbor and this little label netted—fifty-one refills and the result—the druggist got his, but the Doctor got nothing and further deprived other Doctors of a good fee. There is a moral to "just a little sample," for 1937—Dr. A. R. Reder, in *Illinois Medical Journal*.

MANAGEMENT OF LABOR COMPLICATED BY RECTAL STRICTURE

With a Report of Eighteen Cases

FRED A. KASSEBOHM, M D and MILTON J. SCHREIBER, B S, M D,
New York City

*Director of Obstetrics and Assistant Visiting Obstetrician (respectively), The Harlem Hospital
and The Lutheran Hospital of Manhattan*

Rare entities superimposed upon gestation tend, of their very nature, toward the evolution and ultimate production of uncertain interpretation and management. The success or failure in the occasional case gives to the observer a false perspective correctible only by consulting the experience of others. When the sum total of accessible information is small, conclusions of certain value are drawn with great difficulty. This situation obtains in the problem of rectal stricture in the pregnant or parturient woman. Aside from occasional case reports (striking because of fatalities), the literature is poor and offers little assistance. Individual experience is limited because the complication is rare and seen for the most part in clinics carrying large numbers of colored patients. Over the six year period ending October 1, 1936, eighteen cases of rectal stricture complicating labor were seen by us on the Obstetrical Service of the Harlem Hospital. The case incidence approximates one in 1500. The mortality rate in the group was eleven per cent. Obviously, rectal stricture is a formidable complication in labor, requiring more study than has heretofore been granted to it.

The etiology of rectal stricture is debatable. The problem of the obstetrician transcends etiology. Whatever the causative factor, the obstetric situation is grave and its management a major problem.

It is unfortunate that the diagnosis of rectal stricture is rarely made previous to the onset of active labor (our experience). Several factors account for this. Rectal examination finds its earliest obstetric usage in the determination of cervical dilatation after the onset of labor. There is rarely indication for rectal examination in the prenatal period. The commonly

elicited history of constipation does not suggest digital exploration of the rectum. Constipation is the chief symptom of stricture in its earliest phases yet the patients themselves disregard the condition. There are no dramatic warnings of the presence of stricture. The patient in whom rectal stricture is found never notes the physical character of the stools, the examiner thus being deprived of what might be all-important facts in the history. Where stricture has been of sufficiently long duration to effect constitutional change, the attendant is faced with an emergency of tremendous proportions. The obvious solution to the diagnostic proposition is routine rectal examination early in the prenatal period. Where stricture and rectovaginal fistula coexist, there is no diagnostic difficulty since the presence of fecal matter in the vagina prompts immediate rectal examination, and stricture is thus discovered.

The gross pathologic anatomy recurs with monotonous regularity. The examining finger passes into the rectum a distance of one to two inches when it encounters a dense, annular constriction which narrows the lumen to a diameter of one to two cms. It is impossible to pass the finger through the constriction. Attempts to obtain digital dilatation are futile. We have seen one exception to this. The sensation conveyed to the examiner when he attempts forcible dilatation is that something will give way. It is folly to attempt dilatation of any type by any means since such procedure is invariably followed by definite advancement of the constricting process. Delivery through the birth canal may result in aggravation of a moderate stricture. This is purely theoretical. We have had no opportunity to demonstrate it because we

have had practically no opportunity for follow-up studies

Vaginal examination reveals involvement of the rectovaginal septum and the perineal body. The vaginal floor may be hard and rigid. Where rectovaginal fistula is present, the vaginal orifice of the fistulous tract usually lies close to the

out resistance into the rectum. The strictured area is almost entirely fibrous tissue yielding easily to an extending laceration. The vertex distending the perineum and placing undue stress upon the perineal body contributes to the danger. Wide or bilateral episiotomy may prevent difficulty. The repair of a third degree laceration in

rectovaginal orifice. We have never demonstrated the rectal opening of the tract which probably lies above the actual stricture.

Such is the extent of constriction in the average case that we have but once been able to palpate the cervix or presenting part on rectal examination. Thus one exception permitted considerable dilatation of the stricture without undue effort.

The threat borne by this complication is threefold: laceration, infection, and rupture of the rectum. Lacerations of the vaginal floor, extending through the mucosa and into the pathologic zone in the rectovaginal septum may extend with-

diseased tissue is no sinecure. One case gave a history of such complication in previous labor. After several months she was repaired with a fair outcome.

Infection arises from two sources: fecal contamination due to concomitant rectovaginal fistula, the general depression of resistive processes common to stricture. The mildness of puerperal infection in the presence of fecal contamination of the birth canal is amazing.

Rupture of the rectum in parturition is the natural corollary of the pathologic sequelae of stricture. We have previously described¹ (as has Dorsett²) the coprostasis and static ulceration of the rectum

which occur with stricture. Weak, thinned-out, ulcerated areas in the wall of the rectum will not withstand the stress of parturition. The possibility of the rectal tube, used in administering enemata, being thrust through such diseased areas must be considered.

Certain facts of interest are obtainable from Table I. In the eighteen cases there was but one white patient. This is the usual experience. The ages of the patients extended from twenty to thirty-four years. There were four primiparae. The Wassermann was positive in thirty-eight per cent. There were eleven normal pelvises, five generally contracted (in no instance was the true conjugate below ten cm.), and two funnel pelvises. Four cases presented both rectal stricture and rectovaginal fistula. In addition, one case was found to have a chronic ulcerative proctitis.

In each case, there was obtainable a history of long-standing constipation but no patient had reliable information concerning the character of the stools. No patient was certain as to aggravation of constipation following previous delivery and no patient associated fistula with previous birth injury. The multiparae reported from one to five previous deliveries, all spontaneous. All previous puerperia were normal with two exceptions (We were unable to determine previous morbidity). In one of these, there was a postpartum parametritis and in the other a third degree laceration.

The vertex presented in seventeen cases and the breech in one. With the exception of one occiput transverse, all vertex presentations were anterior.

Fifteen cases delivered spontaneously with one death, a mortality of six per cent. There were three operative deliveries with one death, a mortality of thirty-three per cent. If, to our three operative cases we add those of Dorsett, also Games and McDowell⁸ (we have been unable to find any other reports in the literature), we attain a mortality rate of sixty per cent for cases of rectal stricture delivered operatively.

Morbidity was present in fifty per cent of the cases. In each instance the infection was mild and self-limited and no morbid case remained in the hospital beyond fourteen days. There was but

one fetal death, a two pound fourteen ounce premature.

The operative deliveries of which we have knowledge may be briefly mentioned. Dorsett's case was delivered by low forceps. Games and McDowell attempted delivery by low forceps and completed delivery by version and extraction. Of our cases, two were mid-forceps, one for deep transverse arrest, and the other for arrest at mid-pelvis with the vertex presenting as occiput anterior. One of these was the case above mentioned in which the rectal stricture was found readily dilatable. Our third operative case was delivered by cesarean section. She had had a third degree laceration with a previous delivery.

Necropsy was performed in three cases. In each instance, rupture of the rectum was found. This finding may well be predicted.

The facts as stated adequately define the gravity of this complication. The mortality figures, sixty per cent in operative and eleven per cent in spontaneous delivery (this latter entirely our own experience), are little short of astounding.

The key to the situation is early diagnosis. Every pregnant woman must be examined rectally as early as is possible in gestation. Upon the discovery of rectal stricture, alone or in combination with rectovaginal fistula, therapeutic abortion should be advised and following it, early surgical intervention. Where this is impractical (the religious viewpoint may enter) pregnancy may be permitted to proceed with elective cesarean section as the method of delivery at or shortly before term.

In the case first seen in active labor, the question of section may be complicated by other factors such as length of labor, condition of the membranes, etc. Certainly enemata should be avoided to prevent accidental rupture of the rectum. Where there is fecal contamination of the birth canal there should be no attempt at cleansing. This will serve only to advance infection higher in the canal. Labor should be conducted by abdominal examination and, at all odds, spontaneous delivery sought. Wide or bilateral episiotomy is advisable. If spontaneous delivery is impossible, if indication for operative intervention arises, cesarean sec-

tion is the procedure of choice. Where intraperitoneal cesarean is feasible, sterilization should be performed. If conditions are such that extraperitoneal section is indicated, sterilization must wait a later time.

Conclusions

Rectal stricture complicating labor is one of the most formidable problems of obstetrics.

Early therapeutic abortion is advisable when diagnosis is made early. Cesarean section is the best means of accomplishing delivery. It should be an elective proce-

dure. Where election has not been possible the patient, if permitted labor, should be delivered spontaneously. Indications for operation are best met by cesarean section. All cases should be sterilized at section if operative technic permits.

JAPAN'S BAD HEALTH SLUMP

The Association for Encouraging Science in Japan, in response to the general expressions of dismay about the fall in the level of the national health, held its first meeting to consider methods for coping with the regrettable situation. Medical experts from the cabinet departments, the deans of the medical departments of the imperial universities, and experts who were members of the association were present. It was decided to establish four sections of activity: eugenic, physical training, food, and clothing and shelter. The tuberculosis death rate is higher in Japan than anywhere else in the world, according to a letter from Japan appearing in the *AMA Journal*. More than 130,000 cases of acute

infectious diseases occur every year. Dysentery has shown a yearly increase. Trachoma and parasitic diseases are decreasing among students, school children and conscripts, but myopia and decaying of the teeth are increasing remarkably. Mental disease has also increased of late. The number of insane at present is 83,366, which means that there are more than twelve cases of insanity per 10,000 of population. The number of conscripts who pass the physical examination is decreasing every year, and the military authorities are afraid that half of the youth will be unable to pass the examination next year, in ten years this would bring about an alarming situation.

CHAMPION BLOOD DONOR

Raymond Briez works in the public markets of Paris, but he also has a thriving business of his own. He engages in the manufacture of blood, and since he entered the business in 1924 he has sold 257 quarts.

The output of Briez's human factory—his own body—is enormous when one considers that it takes only $7\frac{1}{2}$ quarts of blood to fill the blood vessels of an adult man. During 1935, Briez manufactured enough blood to supply himself and to give ninety-eight transfusions. Each transfusion averaged ten ounces.

The champion blood donor of Paris started his manufacturing business in a small way. In 1924 he gave blood for four transfusions. The next year his orders jumped to thirty-eight. In 1927 the number of transfusions supplied by him attained the astonishing figure of ninety-four and from that time until 1935 he averaged from fifty to sixty a year.

No ill effects have been noted, and Briez is always ready for another call, according to the Paris correspondent of the *AMA Journal*.

LYMPHOGRANULOMA VENEREUM

Report of a Case

BORRIS A. KORNBLITH, A B, M D, *New York City*

Among a series of 105 patients with lymphogranuloma venereum observed at the Mt Sinai Hospital, the following case is one of the most interesting. It was possible to trace the disease from its inception, to locate the partner, and to trace the course from the initial lesion through all its consequent complications.

Case Report

L. G., a forty year old, single, white, Italian porter was admitted to the medical service of Dr. B. S. Oppenheimer, October 1935. He complained of a painful swelling in his left groin of two weeks' duration, continued fever, anorexia, progressive weakness, and a loss of twelve pounds since the onset. He admitted sexual exposure to a negress six weeks before admission. After this exposure, he remembered vaguely a burning sensation upon urination, moderate frequency, and nocturia. These symptoms occurred about five days after coitus and disappeared without treatment in a period of three days. There was no history of any penile lesion.

The patient was well-developed, well-nourished, and acutely ill. He had a temperature of 102° F, pulse ninety. His general examination was essentially negative, except for the local findings. In the left groin there was a diffusely tender mass which measured six x two x two cms. The overlying skin appeared edematous and purplish in color. This mass was apparently an agglomeration of lymph nodes. An indefinable tender, smooth, diffuse tumefaction was likewise felt in the left lower quadrant. This mass was interpreted as an enlargement of the pelvic lymph nodes. On rectal examination this finding was confirmed. A diffuse swelling could be felt digitally on the left side. It extended along the rectal wall as high up as the finger could palpate. Proctoscopy at this time showed no abnormal lesions in the mucous membrane. Smaller lymph nodes were found in the right inguinal region. These were single and well-defined. In addition, there was a moderate enlargement of the posterior cervical, axillary, and left epitrochlear lymph nodes. These were likewise tender. The neurological status showed no

abnormalities. While under observation in the hospital, the left femoral nodes became enlarged. The liver and spleen were not palpable. The spermatic cord was not tender along its course in the scrotum. However, both the cord and its surrounding structures were markedly tender as they entered the external inguinal ring. The patient's temperature ranged between 99 and 102° F.

Laboratory findings. The urine examination was negative. A urethral smear showed no gonococci. The blood urea was fifteen mg per 100 c.c. The blood sugar was 100 mg per 100 c.c. Blood Wassermann and Kahn tests were negative, Frei test was positive (Fig. 1). The hemoglobin was ninety per cent, w.b.c. 8,500, polymorphonuclear leukocytes segmented forms thirty-seven per cent, unsegmented forms per cent, lymphocytes thirty-eight per cent, monocytes two per cent, eosinophiles three per cent.

The patient remained in the hospital for six days and was discharged to the Out Patient Department for further observation. For a period of twenty-one days after his discharge from the hospital, he felt relatively well except for a persistent low grade fever and general malaise. His inguinal glands began to subside, while his axillary and cervical glands had completely resolved. However, he began to complain of a purulent bloody discharge from his rectum. A proctoscopy at this time showed marked edema of the lower eight cm of the rectum. The mucosa was broken by many superficial ulcerations especially in the lower three cm. These ulcerations were covered by a necrotic "diphtheritic mucous membrane." The lumen contained a good deal of purulent material. Another blood count taken at this time showed hgb eighty-eight per cent, r.b.c. 4,200,000, w.b.c. 10,000, polymorphonuclear leukocytes segmented fifty per cent, unsegmented eight per cent, eosinophiles four per cent, lymphocytes twenty-eight per cent, monocytes ten per cent.

Course

The patient was under observation for nine months. During this time the superficial inguinal glands subsided completely, but the pelvic glands were still palpable. He ran a persistent low grade fever. His

Fig 1 Positive Frei test and repeated positive reactions to subsequent injections for treatment

rectal symptoms did not abate, on the contrary they became progressively worse. He passed purulent bloody secretion practically all the time. A progressively enlarging condyloma developed around his anal margin, reaching the size of a lemon (Fig 2). It was particularly painful and interfered a good deal with bowel movement. A digital examination revealed a progressive narrowing which was tubular in character for a distance of about six cm along the rectum. The mucosa in this region at proctoscopy appeared very granular, necrotic, and bleeding profusely throughout. The lesion stopped abruptly at a distance of about six cm. The mucosa in the sigmoid showed no abnormalities. The patient received a total of forty injections of intradermal Frei material without any beneficial effect.

It was possible to trace the partner in this case. She was a negress of forty-two who denied any previous venereal disease. A Wassermann reaction was negative. A Frei test was positive. Pelvic examination revealed a moderate discharge from the cervix uteri. This showed no gonococci. There was, however, a small superficial erosion on the posterior lip. Both patients disappeared from observation.

Discussion

This patient could not remember any local initial lesion, which is a common experience. Only a small group of the total number of cases seen presented themselves with an initial lesion. The lesion was evanescent in the nature of a papule, vesicle, or ulceration on the corona, more

often on the frenulum. The history of urethritis which was undoubtedly not gonorrhea is important. Intraurethral lesions have been described. The urethritis in this case likewise disappeared spontaneously without treatment after a few days duration. The history of contact with a negress was the usual in the series of white men observed. This patient had no other sexual contacts after the exposure to his negro partner.

The incubation period was difficult to determine. A possible time interval of between two and five days may be considered as likely.

In most cases the glandular enlargement was unilateral. However, in all cases giving a history of urethritis as the initial symptom, the enlargement was bilateral. A generalized adenopathy is somewhat uncommon. Two other cases have been observed, one had an initial lesion on the middle finger while the other had a primary lesion on his genitals. Both had a generalized adenopathy which later subsided. The diagnosis in both of these cases was confirmed by a positive Frei test and biopsies, of an epitrochlear gland in the first case and inguinal gland in the other case.¹ Cases with hepatosplenomegaly in association with systemic symptoms have likewise been described.² Pelvic

Fig 2 Perianal condyloma associated with an acute proctitis six weeks after onset

glandular enlargement is undoubtedly present practically to a greater or lesser extent. This may be confirmed clinically, by palpation of the hypochondriac regions, rectal palpation, and palpation of the cord structures as they enter the inguinal canal at the external inguinal ring. When the pelvic glands are involved these structures are tender. The rationale of this sign can be found by considering the anatomical course of the lymphatics.³ There is a direct communication between the superficial inguinal lymph nodes and the pelvic lymph nodes which are retroperitoneal through the inguinal canal. At operation the anastomotic lymphatics, when diseased, stand out as thickened strands as they make their way toward the retroperitoneal space.

There was no breaking down of any lymph nodes in this case, which is not unusual. About forty per cent of the cases observed behaved similarly. There was no breaking down. Instead, a spontaneous regression took place.

The rectal lesions occurring in lymphogranuloma are secondary to the involvement of the pelvic lymph nodes, with a consequent interference with the lymphatic drainage of the rectum. The resulting lesions vary from fistula-in-ano to proctitis, periproctitis, rectovaginal fistula, condyloma, and finally the formation of a fibrous stricture. Rectal lesions are undoubtedly seen more often among female patients and in greater proportion of negroes and Puerto Rican women.⁴ However, many cases are reported among men. The rectal lesion is pathogenetically a secondary lesion. The causative factor is primarily the pelvic glandular involvement. An exception to this, is present among cases of pederasty where the lesion is primary in the rectal mucosa. An un-

usual primary rectal lesion was reported in a child of eight. This lesion was secondary to the use of an infected enema tip.⁵

An increased monocyte count and eosinophilia are not uncommon.

Treatment

In spite of the fact that this patient was given intradermal and intravenous Frei material for treatment, his lesion progressed without abatement. Local adjuvant treatment was likewise given without any beneficial effect. Encouraging results were obtained among cases where the inguinal glandular enlargement dominated the clinical picture, but, consistently unsatisfactory results were obtained in cases where there was any rectal involvement. Further study on treatment is now in progress.

Summary

1 A case of lymphogranuloma venereum with generalized adenopathy and complicating rectal lesions is presented.

2 In view of the number of cases presenting manifestations of a systemic nature a further search for general manifestations is suggested.

3 The use of Frei material, although discouraging in this particular case, offers encouraging results with judicious use in a selected group of cases.

LONG ISLAND DOCTORS MEET

More than 200 Brooklyn, Queens and Long Island physicians and surgeons attended the annual dinner held by the Associated Physicians of Long Island at the Hotel Granada in Brooklyn on Jan 30. The dinner concluded a day of meetings, clinics and professional demonstrations at St. John's Hospital, Brooklyn.

Dr Charles Hamilton, chief of staff of St. John's Hospital, was the host at a

series of clinics during the day. Those who presided at the clinics were Dr John E. Jennings, Dr Augustus Harris, Dr Laurent Feiner, Dr Paul Parish and Dr Carl Green. Dr Leonard Atters, of the hospital staff, gave a pathology demonstration and lecture. Members of the association held their thirty-ninth annual meeting preceding the dinner. Dr John Travis, of Northport, head of the organization, presided.

MENINGOCOCCEMIA WITHOUT MENINGITIS

Report of Case

FRED W GOUNDRY, M D, *Binghamton* and THOMAS H PHALEN, M D, *Johnson City*

Whether meningococcemia without meningitis is a disease entity or an abortive type of meningococcic infection is still an open question. However, we feel that it does occur and possibly more commonly than the cases reported in the literature would lead us to assume. Cases of this disease are described as acute or chronic in type. They may recover after a few days or a few weeks or even after several months duration, either spontaneously or after specific therapy. Then again they may be complicated by meningitis.

It is our purpose in presenting this case to bring to mind some diagnostic features of this disease with a plea for early specific serum therapy, as well as to add another case of this kind to the literature.

Case Report

W K. was a white schoolboy, fourteen years of age. His family history was unimportant. For the past six or eight months, he had frequent spells of dizziness, headache, nausea, and vomiting. His tonsils were removed ten years ago and appendix two years ago. On December 18, 1935, he was admitted to the Charles S Wilson Memorial Hospital, complaining of fever, vomiting, and pain in the abdomen.

On the evening before entering the hospital, while on his way home from the movies, he felt chilly and, upon retiring, had a well-marked chill. Later during the night he had a second chill with a temperature of 104° F. This was relieved somewhat by an enema and hot drinks.

Before coming to the hospital, he was seen by one of us (G) and on examination, he was listless, sweating profusely, temperature of 101° F. He complained of some frontal headache and pain in the right knee. He had no rash, no stiffness of the neck. His nasopharynx was injected. His chest was clear and heart normal. There was moderate distention of

the abdomen with generalized tenderness, more in the upper half. No masses were found on palpation or percussion.

Two hours later, on admission to the hospital, he had a temperature of 100.4° F, pulse of eighty-eight, and respirations of twenty. His face was flushed, he was drowsy, and seemed acutely ill. The pupils were dilated but reacted normally, the sclera and conjunctiva were clear. Ears were normal. The nasopharynx was injected and the tongue coated. There was no stiffness of the neck. Lungs and heart were normal. The abdomen was slightly tender throughout. The liver was not enlarged and the edge of the spleen was barely palpable. On the skin over his chest, abdomen, and upper extremities there were numerous rose-colored macular spots which were discrete and seemed to fade under pressure, suggesting typhoid or paratyphoid.

Next day the patient felt better but still had some abdominal pain, his spleen was palpable and soft, and he had a temperature of 99°. His stool was negative for members of the typhoid-dysentery group of organisms and no bacteria were recovered from the urine. He had a white cell count of 13,000 with eighty-one per cent polymorphonuclears. A brain-heart infusion culture showed meningococci in twenty-four hours, the patient's serum revealed meningococcic agglutinins. He was moderately sensitive to horse serum. He was desensitized and next day was given twenty c.c. of antimeningococcic serum intramuscularly.

Meanwhile his rash after spreading down over the lower extremities began to fade. He continued to improve, took fluids well, and showed no reaction to the serum given. On Dec 22, four days after admission, he was given a second injection of twenty c.c. of the serum. Two days later he developed a generalized urticaria which lasted for four days. By the time the urticaria had cleared his meningococcic rash had disappeared. His spleen was not palpable. His blood culture was negative and the patient felt well. No further serum was given. Two subsequent blood cultures were negative. He

glandular enlargement is undoubtedly present practically to a greater or lesser extent. soon acted in the same wrong way with her girl. She was sure to have seen her move after bedtime in a certain manner indicating masturbation. She resented to have her daughter study for her examination in another girl's company away from home, and asked me to subject the accused to a detective-like investigation. "What may they do together?" I finally cured her curiosity by—an exaggerated—threat with a possibility of her being the cause of insanity in her children and by explaining to her that her interest did not point to the children's welfare, but to her own need for sexual gratification, which she was gaining at their expense.

To return to our case at hand, this boy of sixteen had discontinued playing, was always unhappy, avoided other boys—and, of course, girls—was endlessly thinking of women and, convinced that his sins could be recognized on his face (which is usually nonsense, but which now, in his vicious circle, was true, since his behavior was a self-betrayal), he was forever embarrassed. He blushed without being outwardly aroused and, when anyone remarked upon his redness in the face, he blushed more and was ready to jump at his "adversary's" throat. But he held blushing as "effeminate" and therefore he was convinced that he was sexually inverted. He had begun several trades and apprenticeships, the last one as a printer, but he gave them up and was roaming around and drifting aimlessly. He could not sleep well and he had lost his appetite and consequently his previous strength and health. And, a sort of unconscious irony directed against his mother, he masturbated now several times daily.

It was a French physician of the eighteenth century who first wrote about masturbation, and several generations of doctors believed, and made the public believe, that it

was the cause of insanity and of many other evils. And later, when the profession found various other, real, causes of psychopathic conditions and acquitted masturbation, the public, always a generation or two behind, continued in this superstition which was difficult to eradicate, especially since there was also a vague idea of sinfulness from the religious viewpoint. As far as I am concerned, I would not absolve this habit entirely. While in itself it is not the cause of mental disturbances, while the fear of its results and the feeling of culpability are more guilty than the auto-erotic act itself, there is no doubt that a great *excess* of it, like all excesses, has its bad, usually temporary, effects.

In this case the mother, losing her head, made a further blunder. She sent the boy to prostitutes and had even a male friend of hers take him there. All that "for his salvation!" Fortunately, the lad was unable to approach the woman or to understand with exactness what it was all about and what was expected of him. He had better luck than the boy in the famous story by the great Russian writer Andreieff. But to what depths an ignorant mother may descend! Hardened as we may be through long experience, it is difficult to avoid a quiver at the filthy thought. But then, is not hell paved with best intentions?

In fine she took him to a medical man, a general practitioner, who acted splendidly. He shooed the mother away from the boy and made her adopt the "Hands off" slogan. He minimized the entire situation to the boy, taught him to fuss less about it, and so on, and really cured him within a short time. And when he sent the mother and her son, separately, to me, I had nothing to do but to praise the doctor and to confirm his work.

ARTIFICIAL INSEMINATION

There has been, from time to time, a good deal of unfortunate newspaper discussion on the subject of artificial insemination and "test-tube babies." Many women have gotten the impression that the method is of frequent value in the treatment of sterility. This is not the case. In normal intercourse the sperm is deposited in the immediate vicinity of the mouth of the womb, and the spermatozoa quickly enter the uterus. At times, however, the secretions or discharges of the canal may make this difficult, so that it is conceivable that in the rare case the

injection of the sperm into the uterine cavity with a syringe would give a better chance of pregnancy. In cases of male sterility—and these furnish the chief excuse for artificial insemination—there is no doubt that the method is of at least some value, for without it the chances of the woman are nil unless she sacrifices her marriage vows. If a woman thinks, however, that a single test-tube insemination is sure to result in conception, she will practically always be sadly fooled.—*Novak, Emil. The Woman Asks the Doctor, Williams and Wilkins Company*

was discharged from the hospital on January 2, 1936, sixteen days after the onset of the disease.

Four months after recovery from this attack, he was in good health, attending school, and carrying on normal activities.

Comment

We have here a case of meningococcemia unaccompanied by meningitis. It began with chills and fever, was accompanied by headache, joint pain, and mental apathy. This was followed by profuse sweating and a generalized rash resembling typhoid roseola. The blood count showed a moderate leukocytosis with a preponderance of polymorphonuclears. Meningococci were found in the blood stream early in the attack. As the

patient improved, the blood cultures became negative. There appeared to be no indication for cultures from the petechia and spinal fluid.

This condition is probably more common than we realize because facilities for blood cultures are not always at hand, and enriched culture media must be used for the isolation of the meningococcus. The physician is often unmindful of this disease and may easily overlook it, especially in the milder cases. The triad of chills, arthralgia, and skin eruption should prompt us to secure an early blood culture. From the therapeutic viewpoint, specific serum therapy seems the treatment of choice.

305 CLINTON ST

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M.D., D.R.P.H., *New York City*

Editorial Note: Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine.

Saved in Time

It is inevitable that masturbation—falsely called onanism—should figure among the causes leading to mental conflicts which determine the health or ill-health of the mind. But most examples that may be offered are complicated with some other difficulties. The following is a simple, clear, typical, and therefore very instructive case.

It is that of a boy of sixteen who is physically without blemish and mentally above the average as far as intelligence is concerned.

There would have been no conflict whatever if his mother had not tried to interfere. As a child he was growing and developing without trouble until she began to "educate" him sexually.

Sexual upbringing is a necessity, but it should be done in the proper way, as a response to the child's needs, as an answer to his inquiries and not in a provocative way. And it is possible only if the parent has gained the full confidence of his or her offspring.

When the boy was about ten years old, this mother who, as I discovered in my conversation with her, was herself sex-hungry, asked him once unexpectedly whether he masturbated. She had to explain to him what it meant. He blushed, did not answer

and ran off to his playmates. But she insisted and the next day and the day after she clung to him, telling him repeatedly how "harmful" this practice was. That is how his attention was attracted to it and how he began to satisfy himself. As time passed he did it more and more. Not that it is certain that without his mother's initial spark the fire would not have been lit spontaneously and that he would not have fallen into the habit. But there might have been little or no conflict in his mind—and that is the main thing.

I have known many mothers who made the same mistake and I often have had to work hard to undo the great harm that followed. One widow watched her two children as a cat would a mouse and sprang gleefully upon their little "sins," always aggrandizing them and enjoying them infinitely. She brought her young son to my office because she thought to have noticed some suspicious spots on his bedsheet. And she had lectured him until he was all but confusion and fright. Just to scold her violently and to tell her that intelligent or make-believe neglect would be the proper attitude, that a child has a right to his own secrets and that she would be wiser to close her eyes upon them, had no effect, as she

advertising by the specialist at the expense of his fellow practitioners, and his failure to use common sense? First, the physicians who had referred the cases to the specialist soon discovered that the specialist had maligned them. That was the last case that specialist would ever get from any one of those men. These men told their friends in the profession the story. The other men, realizing that they too might become subject to an action for malpractice, concluded that discretion, if nothing else, required that they should send their cases to some other specialist. The fellow specialists of the offending specialist were outraged because this loose, idle talk was a reflection upon them. The result was that the offending specialist lost caste with his fellow specialists. It became necessary for the members of the committee to warn the offending specialist of the damage his idle talk had caused, so that his self-respect and vanity were wounded. Incidentally, when the doctor discovered how much damage he had done, he went to the rescue of the general practitioners in the malpractice cases. That meant that he had to repudiate what he had told his patients, and the result was that the patients felt, and rightly so, that his word was of no value, and they became irate at the doctor. Briefly summarized, everybody was mad. No medical man with any pride wants himself placed in this position.

I may also point out that only recently a country newspaper in this state was subject to a suit for libel because it had the following to say about a young doctor who had just moved into the community to start out in the world. The newspaper said that he came to the—mentioning the village—"apparently to complete a medical and surgical apprenticeship." The only difference between libel and slander is that one is written and the other is spoken. Most of us have heard, at some time or another, some reflection coming from the lips of a medical man against his fellow practitioner, in which language far more vigorous than that used by the newspaper to which I have just referred, was used.

It is not for a young lawyer to preach to you upon this subject. What I have said was said, not with the thought of attempting to preach to you, but simply in the hope that the mentioning of to actual cases might emphasize the perils that follow the breach of this salutary

rule, and the comfort a physician may take in the thought that he has followed it.

2 Be careful about what you write to your patient

If I may be facetious for a moment, I will recall to your minds the story of the millionaire Broadway playboy, who always addressed his communications to his chorus-girl friends as follows "My dear Susie and Gentlemen of the Jury." When I was a student in law school, I had impressed upon me in the most unmistakable fashion the following rule: *Never write a letter that you would not want read to a jury.*

The rule which I have just given you applies with particular emphasis to the members of the medical profession. From time to time patients move, perhaps in the midst of treatment. They may be attached to the attending physician and attempt to have him follow the case by correspondence. Surgeons frequently operate upon patients from outlying sections who return to their homes before a complete recovery has occurred, and find it necessary to correspond with the surgeon. Vacations, either by the doctor or a patient, sometimes give rise to the same situation.

An actual case will illustrate the point. A surgeon of considerable ability amputated a patient's breast. Following her hospitalization, but before she had entirely recovered from the effects of the operation, the patient proceeded to her home in the country some distance from the point where the surgeon lived. She began to experience some discomfort at the site of the operation and wrote the surgeon to that effect. The surgeon replied assuring her that her fears were groundless, but the patient persisted by mail and the surgeon insisted by mail. Finally the surgeon decided to end the correspondence by writing a firm missive in which the patient was taken to task somewhat for her unnecessary fears and for needlessly troubling the surgeon with unnecessary correspondence. When the patient read the surgeon's letter she consulted another surgeon who, upon investigation, discovered a large surgical pack in the incision. The new surgeon removed the pack, the patient made a speedy recovery and promptly filed a claim for malpractice against the attending surgeon.

Since the celebrated case of *Blackburn v*

MEDICOLEGAL COUNSEL

ROBERT DINEEN, *Attorney, Syracuse*

In this paper I have laid down certain general rules or principles for the guidance of medical men engaged in the active practice of their profession. I make no claim that these rules or precepts are original with me. They have been culled from books on the subject, such as Mr. Lloyd Paul Stryker's work "Courts and Doctors," from decisions of the Courts, from the experiences of lawyers in their various contacts with the members of the medical profession, and from the experiences of my own firm in handling physicians' malpractice cases, dentists' malpractice cases, contested workmen's compensation proceedings involving medical questions, and actions on life insurance policies, and the defense of personal injury cases. Like all general rules, they have their exceptions. They are not laid down here with the thought that they are inflexible, or that they should be followed religiously in every case. They are offered, however, for your general guidance. They are based, either in whole or in part, upon the premises that a doctor's encounters with the law or lawyers should not be unpleasant or distressing, if he will keep three things in mind:

1. He is a member of a dignified and honorable profession.
2. Common honesty always pays dividends.
3. Common sense is a virtue.

Mindful, therefore, of these three truisms, I shall enumerate these rules or precepts, not so much upon the theory that they will help you solve problems, but what is more important, will help you avoid creating them. But, before enumerating these precepts, may I say one thing? In stating these precepts, I have illustrated each one with an actual case, in which of course no names, places or dates are mentioned. If these so-called "horrible examples" should aggregate a sizeable total, you must re-

member that they reflect the exception, not the rule. Each one was caused or precipitated by a departure from, or at least a failure to adhere to one or all of the three general principles which I have just enumerated. They are offered with no thought or purpose of casting any reflection upon the integrity of the medical profession as a whole, or even upon a substantial part of its membership. The precepts follow:

1. Don't run down your brother physician.

In this world it is rare to find two men of equal ability in medicine, as in other fields, background, training, experience, initiative, courage, resourcefulness, ingenuity—all play a part in making one medical man the superior of his brother practitioner, or the inferior, as the case may be. While you may recognize the shortcomings of a fellow practitioner, the public may not. Every time you belittle your brother physician, or disparage his ability, you break two of the fundamental principles that I ask you to bear in mind throughout this paper. You impugn the dignity and the honor of your profession, and you violate plain common sense. To illustrate:

Several years ago in a certain city three malpractice cases were brought within a very short period of time. In investigating these cases a significant fact was discovered, namely, that in each case the initial attending physician had referred the case to a specialist, and in each case it was the same specialist who saw the patient. Further investigation disclosed that in each instance the specialist, in an effort to impress upon the patient his superior skill and learning, had pointed out to the patient how inept the previous treatment had been, or how far superior the treatment of the specialist was to that of the original attending physician who had referred the case to the specialist.

What was the result of this undignified

Read at the Annual Meeting of the Fifth District Branch of the Medical Society of the State of New York, Rome, October 1, 1936

advertising by the specialist at the expense of his fellow practitioners, and his failure to use common sense? First, the physicians who had referred the cases to the specialist soon discovered that the specialist had maligned them. That was the last case that specialist would ever get from any one of those men. These men told their friends in the profession the story. The other men, realizing that they too might become subject to an action for malpractice, concluded that discretion, if nothing else, required that they should send their cases to some other specialist. The fellow specialists of the offending specialist were outraged because this loose, idle talk was a reflection upon them. The result was that the offending specialist lost caste with his fellow specialists. It became necessary for the members of the committee to warn the offending specialist of the damage his idle talk had caused, so that his self-respect and vanity were wounded. Incidentally, when the doctor discovered how much damage he had done, he went to the rescue of the general practitioners in the malpractice cases. That meant that he had to repudiate what he had told his patients, and the result was that the patients felt, and rightly so, that his word was of no value, and they became irate at the doctor. Briefly summarized, everybody was mad. No medical man with any pride wants himself placed in this position.

I may also point out that only recently a country newspaper in this state was subject to a suit for libel because it had the following to say about a young doctor who had just moved into the community to start out in the world. The newspaper said that he came to the—mentioning the village—“apparently to complete a medical and surgical apprenticeship.” The only difference between libel and slander is that one is written and the other is spoken. Most of us have heard, at some time or another, some reflection coming from the lips of a medical man against his fellow practitioner, in which language far more vigorous than that used by the newspaper to which I have just referred, was used.

It is not for a young lawyer to preach to you upon this subject. What I have said was said, not with the thought of attempting to preach to you, but simply in the hope that the mentioning of actual cases might emphasize the perils that follow the breach of this salutary

rule, and the comfort a physician may take in the thought that he has followed it.

2 Be careful about what you write to your patient

If I may be facetious for a moment, I will recall to your minds the story of the millionaire Broadway playboy, who always addressed his communications to his chorus-girl friends as follows “My dear Susie and Gentlemen of the Jury.” When I was a student in law school, I had impressed upon me in the most unmistakable fashion the following rule. *Never write a letter that you would not want read to a jury.*

The rule which I have just given you applies with particular emphasis to the members of the medical profession. From time to time patients move, perhaps in the midst of treatment. They may be attached to the attending physician and attempt to have him follow the case by correspondence. Surgeons frequently operate upon patients from outlying sections who return to their homes before a complete recovery has occurred, and find it necessary to correspond with the surgeon. Vacations, either by the doctor or a patient, sometimes give rise to the same situation.

An actual case will illustrate the point. A surgeon of considerable ability amputated a patient's breast. Following her hospitalization, but before she had entirely recovered from the effects of the operation, the patient proceeded to her home in the country some distance from the point where the surgeon lived. She began to experience some discomfort at the site of the operation and wrote the surgeon to that effect. The surgeon replied assuring her that her fears were groundless, but the patient persisted by mail and the surgeon insisted by mail. Finally the surgeon decided to end the correspondence by writing a firm missive in which the patient was taken to task somewhat for her unnecessary fears and for needlessly troubling the surgeon with unnecessary correspondence. When the patient read the surgeon's letter she consulted another surgeon who, upon investigation, discovered a large surgical pack in the incision. The new surgeon removed the pack, the patient made a speedy recovery and promptly filed a claim for malpractice against the attending surgeon.

Since the celebrated case of *Blackburn v*

Baker was decided, the chances of successfully defending a surgeon who has inadvertently left a pack in a surgical incision have been greatly improved, but not when the surgeon has built an open and shut case against himself by the writing of inept letters. In this respect there has been a fairly recent development in the law, namely, the liability which attaches for information negligently given. Although I have found no case in which this rule has been applied to a physician, I think the day may come when the Courts will hold that where a person acts upon information given to him by a physician in a written communication to his damage, and the information is incorrect, an action may lie against the attending physician for the information negligently given. Discourtesy in correspondence many times leads to costly results, and the same result may be obtained by unnecessarily taking or maintaining a position in correspondence with reference to treatment of a case.

Be careful about placing the collection overdue accounts in the hands of a collection agency

In asking you to observe this rule, I make no effort to further the cause of the legal profession by suggesting, even indirectly, that your accounts should be turned over to a lawyer for collection rather than to a collection agency. My warning is motivated by a different reason.

The average collection agency is run by individuals who hope to collect as many accounts as possible without the necessity of engaging a lawyer to assist the collector in his efforts. You can readily see that even a collection agency that finds it necessary to employ counsel, must pay the counsel, which produces a corresponding reduction in the profit of the agency. The more accounts the collection agency can collect without engaging counsel, the more profitable the agency is. The result is that the collection agency leaves no stone unturned to collect the account itself. Pressure of the most extraordinary kind is exerted. *First*, a series of letters, each more threatening in its tone. *Second*, a series of personal calls by a professional collector, each apt to be more acrimonious than the preceding one. *Third*, the use of suedolegal documents to frighten the

debtor. Now we apply these tactics to the collection of bills for medical services rendered.

Let us assume that a doctor sends fifty overdue accounts to a collection agency. Let us assume that in twenty of the cases he obtained an excellent result. Let us assume that in twenty of the cases he obtained a fair result. Let us assume that in ten of the cases he obtained poor result. Twenty of the cases, therefore, will probably, assuming that they are financially able to, meet the demands of the collection agency. Perhaps a certain percentage of the cases in which the results were only fair or poor will also accede to the demands of the agency, but in that group you are bound to find, on the law of averages, some people who will resent the action of the collection agency and will employ counsel to resist.

In defending such cases, counsel always looks for some affirmative defense. The patient, besides being disgruntled at the collection agency, is disgruntled with the doctor, and the result is that an action for malpractice is either started by the debtor, or else, in the event that suit is brought to collect the account, a counterclaim for malpractice is interposed. One of the most fertile causes of malpractice cases is the injudicious attempt to collect accounts which might better have been forgotten, or else the intemperate efforts of collection agencies to force collection in cases where, even though there was no malpractice, the results were far from satisfactory.

Do not misunderstand me. I am not advising any one here to forego collecting any account, nor am I suggesting that merely because an unfortunate result has occurred, the doctor should work for nothing. What I am saying is that if there is any doubt in your mind about the propriety of your treatment in any given case, if you must send your bills to a collection agency for collection, leave the bill out in that particular case. Out of any number of cases, I mention a typical and actual case involving this very situation.

A dentist who had a very bad result in a case let the bill drift for about one year and eleven months before making any effort to collect. You must remember that the statute of limitations on a malpractice case is two years. The dentist knew that the patient was disgruntled with his treat-

ment. All the dentist had to do was to wait a little over a month if he still thought he ought to be paid, and the statute of limitations would have barred the patient from pleading malpractice as a defense to the dentist's action to collect for his services. Instead of using common sense and letting the statute of limitations expire, the doctor made a vigorous eleventh hour attempt to collect his fee—with what result? Two days before the expiration of the statute of limitations, the patient sued the dentist for malpractice.

The dentist may be able to successfully defend this case, but the fact remains that by his failure to use common sense, he has precipitated a malpractice case which otherwise never would have been brought. On the other hand, I do not want you to feel that I am telling you in every doubtful case you should wait until the expiration of two years before you attempt to collect your bill. Sometimes in the defense of malpractice cases the fact that the doctor has failed to send a bill has been developed in evidence, indicating that even the doctor himself had doubts about the propriety of his treatment, or he would have attempted to collect the bill. No two cases are alike. What might be the right thing to do in one case would be the wrong thing to do in another, or vice versa. The point I make is that if there is any doubt in your mind about it, take counsel, and, to return to the heading of this point, take the counsel before you send bills out in doubtful cases to collection agencies.

4 Use care in keeping your office records. Insist that the hospital in which your patients are confined uses care in maintaining the records.

It is surprising how important the admonition contained in this rule is, and how careless many doctors are about it. If I succeed in nothing else today but impressing upon your minds the importance of this rule, I will feel that the day has been well spent. The reasons why this rule should be most carefully followed are many and varied.

To begin with, this is an era of litigation. People are becoming what is known as "claim wise." Actions are started on cases nowadays that would never have been dreamed of years ago. A doctor never knows when his knowledge of the case may

furnish the turning point in litigation involving, perhaps the rights of the patient, and sometimes the very professional life of the doctor himself. Let us consider the former.

A patient is injured in an automobile accident. He comes to his attending physician, the attending physician examines him. If his records are complete, he will mark down the history of the accident, the complaints of the patient, his findings, his treatment, and as the case progresses, a report on the progress of the case, and I hope, an itemized statement of the calls made and the value thereof, so that the doctor may ultimately be reimbursed for his efforts. What happens when the doctor fails to do this and litigation arises? Perhaps the litigation may turn upon the history of the case. The history of the case given by the patient to the doctor and set down on the doctor's office records, may often corroborate the patient's claim as to how the accident happened, thereby enabling the patient to recover a verdict which he might otherwise lose. In such a case the patient is grateful to the doctor because the accurate records of the doctor have enabled the patient to be compensated for his damages.

On the other hand, the patient may be seeking to collect damages on some description of an accident entirely different from that which he gave the doctor in the first instance, before there was any thought of litigation. In such a case, if the doctor is called to court and is compelled to produce his original history, the doctor is in the position where, while the stating of the history may result disadvantageously to a claim asserted by his patient, at least the doctor will have the satisfaction of knowing that due to the accuracy of his records, no injustice has been done to the opposing party in the lawsuit.

The same is true of the doctor's findings and of his reports on the progress of the case. Failure to keep these records may subject you to some unpleasant moments on the witness stand, because in this day and age doctors are expected to keep good records, and when a doctor fails to do so, many jurymen feel that the doctor is behind the times or careless, or even sometimes dishonest, feeling that the doctor has intentionally omitted the history, lest it have an adverse effect upon his patient.

All these considerations reflect upon the

integrity of the profession, and certainly may affect the doctor's following, because even jurymen from time to time have occasion to consult physicians, and they certainly are not going to employ the services of some doctor who made an unfavorable impression upon them because of his slipshod and careless method of doing business.

If it is important to maintain up-to-date and complete records for the benefit of your patients, it follows necessarily that it is doubly important to maintain such records for the benefit of the doctor himself. The most disconcerting thing which a lawyer engaged to defend a doctor in a malpractice case can find is incomplete or carelessly kept office records or hospital charts. The importance of a properly kept office record can not be overemphasized in the defense of such cases. It is frequently the hub of the lawsuit. If the record is complete, modern and up to date, the jury is apt to conclude that the doctor's treatment was in the same category, and may decide the case in the doctor's favor. On the other hand, if the doctor is charged with carelessness or neglect, and his office record looks the same way, the jury is apt to infer, not rightly perhaps, that the doctor treated his patient as carelessly as he took care of his records.

A word of warning! If you have been careless in keeping your office records and you are suddenly confronted with a malpractice case, do not attempt to supplement the deficiencies in your office record after the trouble has begun in order to fortify your position. In giving this word of advice, I am proceeding upon the premise, that the doctor, in revising his record, has not set forth any items therein which could not properly have been there in the first instance. An actual case will illustrate the perils of this procedure.

Several years ago a doctor was sued for malpractice. His office record was most incomplete. Before the attorney furnished by his malpractice insurance carrier arrived on the scene, the doctor proceeded to supplement the deficiencies in his records. The case was several years old, and in so doing the doctor lost sight of the fact that the ink which he used was not the same color as the original ink on the record. Further, it was apparent from even the most casual inspection of the record that recent additions had been made to it, although the doctor had not treated the patient in months. Then too, the doctor,

in writing in the notations, from force of habit, put down the same year in which he made the notes, although the treatment was rendered the year before. The attorney for the plaintiff subpoenaed the doctor's record, and the result was that when the jury inspected this record in their jury room, they discovered the situation and promptly concluded that the doctor was attempting to cover up, and returned a verdict against him.

Besides that, such activities destroy the confidence of the attorney in the case. He feels that the doctor has been underhanded, or at least injudicious, and he has no way of knowing what other changes, either in the record or in the case itself, the doctor has made. A lawyer, in order to successfully defend any case, must know the truth by all means, and if he can not believe what his own client tells him, his task is rendered much more difficult.

What I have said about office records applies with equal force to hospital records. In the average malpractice case, as soon as the case is sued, the defense attorneys usually have a complete copy of the hospital chart made. An actual case will illustrate the perils of tampering with a hospital chart.

In one case a nurse, anxious to protect a doctor who was charged with neglecting his patient, added several calls by the doctor to the hospital chart. Prior to the time she made these changes, the attorneys for the doctor had made copies of the hospital chart, and when the two were compared the additions were discovered. To make matters worse, the additions gave every indication of being of recent origin. Fortunately for the doctor, upon the trial his adversary did not examine the record closely enough to discover this change in the record. The doctor was not responsible for it, in any event. Fortunately the result in that particular case turned out to be satisfactory. However, it might well have been disastrous. In the large hospitals in the cities, it probably would have been difficult, if not impossible, for the nurse to have obtained this record for the purpose of making changes, but in the smaller hospitals where less rigid care is kept of these charts, such a situation is possible, and as I have just pointed out, actually does occur.

It is a great comfort when you are confronted with a malpractice case and charged

with failing to do some particular act, or improperly doing some act, to be able to pick up a hospital chart and establish by written evidence made at the time, that the charge against you is groundless. On the other hand, it is a source of considerable distress to turn to the hospital chart in an effort to find evidence which will fortify you in the defense of one of these cases, and find such evidence missing. The failure to insist upon up-to-date hospital records is particularly inexcusable when you consider that most of the entries therein need not be made by the attending physician, but by the employees of the hospital, nurses, etc

5 Keep up-to-date

All of us like peace of mind. There can be no peace of mind, however, in the belated discovery that after a patient has suffered intense pain, prolonged disability, or even death, the situation might have been obviated had the physician known of some modern treatment which was readily available in the literature of the day. However, I approach the problem, not from the standpoint of peace of mind so much as from the standpoint that failure to keep abreast of the times may expose you to liability for malpractice. The law in this state has long been established that such a failure to keep abreast of the times, if it results in damage to the patient, subjects the doctor to liability in an action brought by the patient.

It is always rather disquieting, when a lawyer is called upon to defend a doctor for failure to keep abreast of the times, to enter the doctor's office and, instead of finding an up-to-date library on the doctor's shelves, and up-to-date periodicals on his desk, to find instead a number of time-worn relics thickly covered with dust and giving indication of not having been opened for years. While you may not think some pa-

tients notice these things, in a small community where doctors are well-known, failure to keep abreast of the times is frequently common knowledge, and may be known even to members of the jury who are called upon to decide his fate. I mention two illustrations upon this point.

In one case a doctor was baffled in attempting to arrive at a diagnosis. It so happened that he was a keen student of the medical journals. In reading these journals he came across several case histories in other parts of the country involving the identical symptoms, which were finally traced to a depilatory cream. This discovery finally furnished the basis for a lawsuit in favor of the patient against the manufacturer and retailer of this cream. Had the doctor failed to keep abreast of the times, he might never have been able to diagnose the plaintiff's condition, nor would he have been able to furnish the patient information which enabled the patient to bring action to collect for her damages.

A second example illustrates another point. In one malpractice case the attending physician's treatment was anything but modern. There was a celebrated textbook on the subject, numerous editions of which had been published since the doctor had bought his original copy. A number of changes had been made in the treatment. Had the doctor known of these changes, his treatment might have been much more effective. His patient died, and after the patient died the doctor purchased the latest edition of the book. When he was called upon to defend himself in a malpractice case, he knew the subject then, but it was too late. At the time he should have known it, in other words, at the time when he could have saved the patient's life, the latest copy of the work was resting, not upon his desk, but upon the shelves of the bookseller.

WHAT DID HE DO IN HIS SPARE TIME?

An interesting example of contract practice recently came to our attention from a fair sized city in Illinois. One physician received the contract for supplying necessary medical care to the indigent for the sum of \$1,400.00 per year. He furnished all drugs and supplies, his annual report shows that during the past year he pulled 542 teeth, performed five hysterectomies, seventy-two other abdominal operations, at-

tended fifty-five obstetrical cases nearly all of them in the homes. During the year he recorded 5,703 office visits, 3,223 residence calls, sixty-six visits to the county home, fifty-seven police calls, fifteen to the county jail, and 177 calls to the rural districts, the distance varying from eight to twenty-three miles each. It is quite obvious that this contract physician actually earned the money which was paid for his services.

EDITORIALS

A Federal Department of Health

We have advocated a federal department of health in the ensuing and pending reorganization which is under consideration in Washington. We would deplore the establishment of a health bureau in a federal department of welfare. Not in any way abrogating the principle of local responsibility, and the necessity of local and state administration of health laws and preventive medicine to the utmost degree, and also comprehending the differing nature of communities which inevitably involves differing methods of providing health safeguards, we contend that such a health department is a necessity now and should concern itself with planning for medical care to the indigent, including pay for the physicians serving them, the care for the physically and mentally handicapped, the planning to deliver *high quality* of medical care and service to the lower income group, (not by the adoption of a foreign insurance scheme, but by developing an American plan in keeping with our traditions) by planning for the medical aspects of child welfare and maternal care, planning safeguards for the care of the industrial worker, including supervision, inspection, and control over the hazards of occupation, supervising hygiene and sanitation in school, factory, farm, mine, and

home. The integration of all public health functions under one coordinating head is needed. These and other functions stress the necessity of such a federal health department. The administrative head of such a department should be a doctor of medicine with experience and qualifications as an executive.

Having some such idea in mind, the Executive Committee, at its last meeting, unanimously passed the following resolution:

Resolved "That the Medical Society of the State of New York urge that the reorganization of the Federal Government combine in one department all medical and health activities making this a separate and distinct department, and urge especially the nomination as chief executive officer of such a department of a qualified physician with a record of achievement in administration."

We ask our members to bring this resolution and what it implies to the attention of our legislators, so that the medical profession can better serve the public, enhance the extent of preventive medicine, and still further improve our morbidity and mortality statistics in the fine records of which we as physicians take so great a pride.

The Amended Constitution and By-Laws

The first draft of the amended constitution and by-laws which the committee charged with this revision presents to our membership is before you

In his address before the House of Delegates, Dr Charles Gordon Heyd, former president of the Society, commented on the outgrown machinery of government under whose framework we were functioning, and called attention to the need of changes in our fundamental law and to the By-Laws within the framework of which we were trying to meet the urgent needs of new and unthought of conditions—conditions which were never envisaged when our Constitution and By-Laws were adopted

Originally our society had little of actual business management on its hands. Professional colleagues came together and discussed scientific problems mostly, and concerned themselves with questions of establishing standards and arranging modes of medical practice. To be sure, dispensary abuse, ethics, and the ever-present fight to protect the public from quackery, cultisms—onslaughts against the medical practice law were ever pressing problems. No one visualized the complicated set-up necessary for the coordinated effort and medical integration necessary to properly deliver to the public concerned the benefits designed for it by the new Workmen's Compensation Law. The management of a medical journal changed from a medium for presenting scientific papers written by those experienced in the clinical and laboratory workshops of the profession, to an administrative effort to produce a journal of opinion, expressing the formulated policies of the legislative section of our society, its officers, and its committeemen. The study and scrutiny of proposed legislation in the State's legislative halls, became a very heavy duty because of the tendency of the times which impels our State officials to respond to both popular and pressure-group demands for specific

bills. We, as an organization, experts as it were in both preventive and curative medicine, need and do support the public health officials in their worthy endeavors to better the living environment of our people. Our embarkation upon an endeavor to enhance the continuing education of our profession, and bring outstanding teaching personalities to our rural and other centers remote from our great medical teaching centers, demands coordination and control. The radio, the press, the lecture platform, and the lay magazines each present a problem to us, needing study and continuous action. Then, about a decade ago, there developed groups of sociologists who, sensing a wrong in the handicaps under which the underprivileged lived and worked, hastily and without due consideration of the true factors at fault, proposed and pressed for legislative reforms which, had they been enacted into law, would not only have profoundly changed the whole medical scene, but conceivably have had a deleterious influence upon the very background of our parliamentary form of government. Hence it became necessary to form a group which furnished documented and authentic information to the law-makers, to the profession itself, and to the public, upon the instant issues before it. These are only a few items, hastily sketched to make the background of the picture which the 1936 House of Delegates faced.

The House of Delegates adopted in principle the idea that changes in our fundamental governing structure were necessary and should be carried out, to coordinate our efforts, increase efficiency, prevent overlapping and reduplication of efforts, and simplify control of our various endeavors. To this end, the House directed the immediate appointment of a Committee on Revision of the Constitution and By-Laws, and directed that it present the results of its work to the 1937 House of Delegates for its consideration and action. Our President, Dr Floyd Winslow, heartily undertook the mandate

and appointed the Committee whose work is before you, as printed in the JOURNAL [February 15, 1937, pp 418-430]

In the interim a mandate was given to this, your journal, to publicize the proposed amendments, and make editorial comment on them

While the work of the Committee on Revision is not yet in its final form, nor in the form in which it will be presented to the 1937 House, we gladly comply with the Committee's request to urge every member to study the proposed changes. The Committee would like to feel, as they come before your elected delegates in the next House, and ask adoption for their amendments, that the general membership is in accord with them. They are urgently inviting both criticism and suggestions, and promise that these will receive serious studious consideration and perhaps if found good and convincing, they will incorporate as much of these as they deem proper into the new instrument of government before it takes final form, and is presented for consideration and final action.

We cannot express any opinion upon the proposed changes, but we will from time to time, between now and the meeting of the next House, present explanatory editorials as either the Committee or the correspondence upon this topic shows it to be necessary.

Read, study, criticize, and communicate with Dr O W H Mitchell, Chairman of the Committee on Revision

The Fight Against Syphilis

Finally, after many years of tireless effort on the part of organized medicine and public health officials, the fight against syphilis has been brought into the open. The public is being informed of the ravages of this disease and the word "syphilis" has been permitted to replace the stupid phrase "social disease."

In the present stage of this campaign, "adequate treatment" is the adequate treatment

of infected individuals so as to render themselves and the community safe from the spread of syphilis. It is to be hoped that the press and the radio, which are now actively aiding the health authorities, will not lessen their valuable services as time goes on and the novelty of this drive wears off. We will need their support all the more when the preventive side of this subject is reached, for we will then have to cope with all varieties of so-called "defenders of public morals." These latter blind themselves to the inevitable and are like the farmer who said, "I'm open to conviction, but I'm damned if you can convince me." They play an important part in our body politic but their influence must not be permitted to defeat this war against syphilis.

Some More Figures

The vicious phases of health insurance seldom reach the public. Whereas the medical profession, vitally concerned as it is with both the quality and the cost of medical service, is constantly calling attention to the fallacious claims made for health insurance it seems that deaf ears are turned to its warnings by the professional "socializers." Organized medicine must therefore go directly before the people and through them to their official representatives. Since each individual physician must consider himself in duty bound to present the facts to his clientele, we call to their attention vital facts from time to time.

In Austria, wherein 2,000,000 persons, or thirty per cent of the population, are affected by the social insurance law, the Minister of Social Welfare reports that in 1935, twenty per cent of the money collected was spent for doctors' fees, 9.5 per cent for medicines and 14.5 per cent for administration! It is significant that this represents an improvement over the former year. Then, the cost of the medicines prescribed was deducted from the doctor's compensation. Now an agreement has been reached between the prac-

tioners and the *Krankenkassen* to the effect that a quarter of the total income is set aside to cover both medical fees and medicines. But "if a medical man is found to have been too extravagant in prescribing he will have to refund the excess so that 'he personally will suffer and not, as hitherto, the whole profession'"

In the long run, who suffers? Why, the people, of course. Not the doctor who certainly will not jeopardize his meager income by writing a prescription for a needed remedy when he knows he probably will have to pay for it. What is still sadder, however, is that 14½ cents out of every dollar the public is forced to contribute for its health goes to support a hungry bureaucracy. Do we want this sort of thing in our country? Ask your patients!

A Purely Medical Question

As brilliant an administrator as the late Commissioner Hermann Biggs repeatedly declared that a medical education is essential to determine community health needs and inaugurate suitable policies for their satisfaction. A public welfare program that fails to respect the technical requirements of public health work nullifies its own purpose.

For this reason the proposal to subordinate Federal health activities to the general aims of a lay welfare department has aroused a storm of disapproval in the profession. Thoughtful physicians have long urged the consolidation of all national health work in a single administrative unit, but this should be a medical department under the direction of medical men. The lay sociologist has neither the scientific training required to formulate public health policy nor the special experience necessary to administer it properly.

The growing importance assumed by public health problems warrants the establishment of a department devoted

exclusively to this work. Its technical nature demands that control over such a department be vested in qualified medical men. To make public health a minor bureau in a lay department, would seriously jeopardize further progress in this field.

Sensational events have diverted popular attention from the proposed Federal reorganization. Meantime lay groups seeking to obtain control over the public health let slip no opportunity to influence Congress. To counteract such propaganda, physicians should communicate immediately with their representatives in House and Senate to urge the creation of an independent, medically governed Department of Health.

The Annual Meeting

It is not too early to reserve the dates May 24 to 27, for your instruction and for your entertainment in Rochester this year, for the annual meeting of the Society promises a full and interesting program of events.

This year will mark an innovation in that the meeting will not be held in a hotel. The palatial building with their splendid room spaces of the Rochester Chamber of Commerce will be the scene of our activities. Dr. Leo F. Simpson, the Chairman of the Committee on Arrangements, has done a fine job. More of this hereafter. There will be a public meeting on the evening of Wednesday, May 26, in the fine Eastman Theatre which is part of the University of Rochester. The theme for this meeting will be "The Relation of Photography and Motion Pictures to the Science and Practice of Medicine." Dr. Benjamin J. Slater has this matter in hand and it promises to be something not usually found on programs of medical meetings.

Our Vice-Speaker, Dr. James M. Flynn, has charge of the Banquet arrangements. His genial personality and the array of distinguished guests will make this, too, interesting and note-

The Fight Against Syphilis

Finally, after many years of tireless effort on the part of organized medicine and public health officials, the fight against syphilis has been brought into the open. The public is being informed of the ravages of this disease and the word "syphilis" has been permitted to replace the stupid phrase "social disease."

In the present stage of this campaign, the desideratum is the adequate treatment

of infected individuals so as to render themselves and the community safe from the spread of syphilis. It is to be hoped that the press and the radio, which are now actively aiding the health authorities, will not lessen their valuable services as time goes on and the novelty of this drive wears off. We will need their support all the more when the preventive side of this subject is reached, for we will then have to cope with all varieties of so-called "defenders of public morals." These latter blind themselves to the inevitable and are like the farmer who said, "I'm open to conviction, but I'm damned if you can convince me." They play an important part in our body politic but their influence must not be permitted to defeat this war against syphilis.

Some More Figures

The vicious phases of health insurance seldom reach the public. Whereas the medical profession, vitally concerned as it is with both the quality and the cost of medical service, is constantly calling attention to the fallacious claims made for health insurance it seems that deaf ears are turned to its warnings by the professional "socializers." Organized medicine must therefore go directly before the people and through them to their official representatives. Since each individual physician must consider himself in duty bound to present the facts to his clientele, we call to their attention vital facts from time to time.

In Austria, wherein 2,000,000 persons, or thirty per cent of the population, are affected by the social insurance law, the Minister of Social Welfare reports that in 1935, twenty per cent of the money collected was spent for doctors' fees, 9.5 per cent for medicines and 14.5 per cent for administration! It is significant that this represents an improvement over the former year. Then, the cost of the medicines prescribed was deducted from the doctor's compensation. Now an agreement has been reached between the prac

Today the original excuse for licensing physiotherapy technicians no longer exists. Present registrants are protected by the licenses they already hold for as long as they observe the statutory limitations on their activity. There are no recognized training schools in the state to produce qualified new candidates for licensure.

The law as it stands is an invitation to chicanery. Even in the absence of accredited physiotherapy schools, applicants for license still crop up. In almost every case political influence is invoked to compensate for the candidate's inability to comply with the statutory requirements.

There would be no dearth of competent technicians if the Feld-Milmoe Act were passed. As it is, most specialists in physiotherapy, including hospital departments, train their own assistants according to their particular methods and needs. The registered technician is frequently more of a hindrance than a help because of his proclivity to assume responsibilities for which he is not qualified.

As long as the statutory provision stands, inadequately trained technicians will attempt to secure licenses through political pressure and successful candidates will use their licenses to hide unauthorized practices. Repeal of the licensing clause, as proposed in the Feld-Milmoe bill, would eliminate a situation that is as unnecessary as it is unwholesome.

CURRENT COMMENT

"PRIVATE FUNDS IN THE PUBLIC INTEREST" is discussed in an article in the February 15, 1937 issue of *Today* by Raymond Moley. "We now have foundations which concern themselves with the subjects of education, medicine and public health, social welfare, social sciences, physical and biological sciences, economics, international relations, government and public administration, esthetics, humanities, child welfare, agriculture and forestry, city and regional planning and housing, heroism, race relations, religion, engineering, public service,

labor, birth control, civil liberties, aviation, animals, cemetery maintenance and monuments and commemorative celebrations.

"This imposing list may give the casual reader the impression that the improvement of mankind is being pursued with breathtaking thoroughness on all possible fronts. *In reality neither thoroughness nor logic nor reason characterizes the distribution of funds as among these varied fields of human endeavor.* We need not quarrel with the facts that over \$10,000,000 was spent by foundations and trusts in the field of education in 1934 and a like amount in the field of medicine and public health. But it seems incongruous, at the very least, that only \$1,000,000 went to research in the field of economics that same year, only \$750,000 to the study of government and public administration, only \$730,000 to the humanities, less than \$25,000 to labor, less than \$1,500 to civil liberties and less than \$1,000 to aviation. A philanthropist might do worse (and generally does) than to establish a foundation to study the way in which foundations should be established, *for the complete array of funds and foundations in this country is, unfortunately, as much a monument to prejudices and whims of its donors as it is to their good intentions.* It is, besides, in far too many cases, a monument to vanity and shortsightedness."

Nevertheless "it is perfectly obvious that however capricious some of the donors of funds may have been, however unfruitful some of the endowments, private agencies are still better able to do many things than any government.

"Our recent experience with the hue and cry over 'boon dogging' shows how easy it is for demagogues to create prejudice against the expenditure of public money for purposes whose value is not immediately apparent to the average man.

"Purely experimental activities in the fields of education, science, sociology and the arts, activities which require many years for their accomplishment, small-scale unstandardized operations, research and teaching in the higher ranges of knowledge—these are properly subjects for private encouragement. A Pasteur who must make innumerable mistakes before he achieves great ends cannot depend upon the sympathetic understanding of a political administration. * * * An inquiring man by the name of Socrates bears witness to the public's impatience with those who dare to speculate on controversial questions.

"The public interest would be poorly served by the destruction of institutions devoted to research, education and charity, in which there is preserved a spirit of inde-

worthy Suffice to say that if you plan to go to Rochester, plan to stay throughout the sessions and take in the Banquet Finally—take your wife along, too, for the Ladies Auxiliary, under the chairmanship of Mrs J Craig Potter, is planning a program for them too They will be unusually well entertained

Notwithstanding all the emotions evoked by the legislative sessions of the House of Delegates, the Committee reports, the consideration of pressing medicosociologic problems, and the election of officials to carry on this necessary work, nothing to a doctor's mind transcends the opportunity to see and hear, and make personal contact with the leaders of scientific thought in medicine The dull, heavy daily grind, the obstacles to continued adherence to our ideals, and the daily awakening to the knowledge of how much more there is to know, brings us naturally to sit at the feet of the great teachers of medicine New York State, proud in the tradition of its many teaching institutions, is wont to boast among its other blessings, of the fine work of its native sons in scientific medical leadership Dr William A Groat, the chairman of the Committee on Scientific Sessions, has assembled a program which we can modestly term outstanding, and unusual There will be presented a symposium on the Relief of Intractable Pain, and another on Blood The symposium on blood will be led by Dr Geo H Wipple, (a Nobel prize winner) of the Rochester University, W B Castle of Harvard, and Sturgis of the University of Michigan The symposium on Pain will be presented by Drs Louis Cassamajor, Byron Stookey, and James C White of Harvard Medical School

In lighter vein, and as relaxation, there will be a great golf tournament held on Thursday, after the scientific sessions will have finished work The main feature will be a competition between members of various Academies of Medicine for the Lilly Cup Dr John R Williams has this matter in hand and those desiring to compete should address him in

Rochester This competition has been held for the past five years either in Western New York or in Canada This year it is expected that many physicians from Toronto, Hamilton, and St. Catherine will come to our scientific meetings, and stay for this international medical tournament which, while it stresses competition between ourselves and our Canadian neighbor, will none the less add another cementing link of friendship and cordiality between these two "good neighbors"

During the interval between meetings, our members have little contact, and often unfortunately less knowledge of how our democratic State Society actually functions Many are unaware of the time consuming work done gratuitously by many of their elected delegates The thoughtful, serious consideration of all aspects of many pressing problems is hardly appreciated by the membership at large Come and visit your House of Delegates while it is in session, and judge and evaluate how much you owe to these devoted fellow members for the work they do for you and for the public welfare

We doubt saying too much, or over stressing when we point out that *you really cannot afford to miss this meeting*

Revocation of Physiotherapy Licensure

Physicians, educators, and reputable physiotherapists are agreed that the Feld-Milmoe bill serves a good purpose in abolishing the licensure of physical therapy technicians When the licensing clause was enacted, the medical profession accepted it to prevent economic injury to a trained group whose livelihood was at stake Subsequently, however, this provision was abused by the creation of a far larger corps of licentiates than had been intended Once licensed, many technicians ignored the restrictions placed upon them by law and practiced independently of medical supervision

Removal of Tonsils by Electric Coagulation

1749 Grand Concourse,
New York City

To the Editor

Permit me to congratulate Dr Joseph D Kelly on his timely article in the Feb 1 issue of the "Journal" entitled "Tonsillec-tomy vs Electric Coagulation—The Present Status" While the majority of reputable specialists have known for a long time the facts as stated by Dr Kelly, the profession in general may not be fully aware of the totally spurious claims made by those who practice electrocoagulation

Just three years ago Dr William J Yonker reported the experience of himself and his associates with this method before the Chicago Laryngological and Otological

Society, concluding with the statement, "Our results have been unsatisfactory, and we are still in doubt as to whether there are any indications for this method of removal of tonsils" This decidedly coincides with my own experience in operating on patients who previously had their tonsils "removed" by coagulation

In the light of accumulated experience it is safe to say that electric coagulation of tonsils is no operation at all and those knowingly practicing this method may justly be suspected of quackery and fraud.

Very truly yours,

JOS POPPER, M D

February 9, 1937

WISCONSIN DOCTORS WITH SHINY PANTS

The effort of state and local authorities to make the doctors provide medical service for absurdly low fees is rather getting on the nerves of the medical men all around the country In Wisconsin an extensive investigation was made to discover and list all children with physical defects, but not "one white dime" was provided to remedy them, and "what's more, no one is asking for such an appropriation," says a Wisconsin physician in a letter to his state medical journal He is Dr Pat Hansberry, of Hillsboro, and he wields a trenchant pen He goes on

I do not in any way censor them for not making this demand, because they have a bunch of glossy-seated, ravel-cuffed, worn collared, unshaved, long-haired M D's all over the State, all members of the STATE MEDICAL SOCIETY who are, and have been, dishing out this service without one dollar to show for their work and are subject to criticism and open for malpractice from this indigent class, for what? GLORY? Where in h--- is the glory?

Then he recalls another imposition that was put over on the doctors last fall, and suggests a program of action

If you shiny-pants friends will remember

there was a big drive last fall as the result of an appeal from the State Board of Health on vaccinations Oh Boy! T B test, smallpox, diphtheria, pin worms and what not, all at one setting The encouraging part of it was, it was to cost the patient 25c and the Darn Doctor got every cent of it. THE GRAFTER took the entire 25c and stuck it down in his shiny pants Such a steal—25c, just to give the banker's kid, the merchant's kid, the judge's kid, the lawyer's kid, the minister's kid,—three vaccinations at one time and then have the nerve to soak them twenty-five cents It is no wonder those Darn Doctors have money, of course, the State furnished the material, all except the skill and experience, that was acquired and didn't cost anything, so I guess it's all right.

I wonder what you think of this article? I don't care what you think,—you can't deny it Of course you stick out your chest and light a cigar that some W P A. worker gave you for a call, and pass as a bond broker, I will bet you a 25c vaccination, you haven't a month's rent ahead Now isn't that right?

Let's get organized to go down to Madison and get some real honest to god bills before this legislation and fight like hell to put it over How about blazing the trail for at least fair play? At least a square deal? At least a decent meal now and then? How about discarding the shiny pants?

pendence and a continuity of operation unaffected by passing political changes

"And yet the public looks with increasing impatience upon *wasteful, futile bequests and upon trustees and professional directors who are afraid or unwilling* to send the funds they control into new and more fruitful fields of enterprise

"The political direction of endowments and foundations can only be forestalled by the introduction of more of a sense of public responsibility into their management and direction

"They can survive and flourish only if they are flexible, susceptible of adaptation to the needs of the times, responsive to the fundamental movements of life and society" (Italics ours)

"It is surely very necessary for the social worker handling or even touching upon medical problems, to understand the basic ethical principles under which the medical profession is supposed to function, and under which it does function to a surprising extent * * * The social worker acts as an auxiliary agent to the physician in the care of the patient and must, with him, observe his ethical rules and must guard her activities so that the physician is not innocently involved by the social worker in an unethical act. The onus, stigma and penalty, if any, is the physician's to bear,

and the worker must guard him against this, as well as guard herself and her own profession against accusation of malfeasance * * *"—Good advice from Dr. C. W. Munger, President of the American Hospital Association

"MEDICINE MIGHT WELL BEGIN by blasting some of the nonsense out of the popular so-called 'mind,' restoring some understanding of, and humility toward the miracle of the human body, and then call attention to the effects of such national conditions as poor housing, overeating or undernourishment, and over indulgence in vicarious exercise, on the public health

"MEDICINE MIGHT WELL BEGIN by blasting bungling interventions of 'social engineers' than any other interest in the whole social complex. At the same time medicine exists in an atmosphere surcharged with more mistaken notions and opaque nonsense about its needs and methods than is the case with any other public service or profession. And, —let it not be forgotten—the public has a great and vital stake in the preservation of foundations of quality in medical care as to the nature of which the general public is almost completely unaware.

"*Carpe diem!*"—The editors of the *Westchester Medical Bulletin*, too, are calling our attention to "the handwriting on the wall"

BLOOD TESTS FOR ALCOHOL IN TRAFFIC ACCIDENTS

The German minister of the interior recently ordered blood tests for alcohol in connection with traffic accident cases. Such blood tests were first experimentally performed under the auspices of the Berlin police administration. On the basis of these experiments it is now stipulated that examination be made of all those persons involved in traffic accidents who are reasonably suspected of being under the influence of alcohol, says the Berlin correspondent of the *AMA Journal*.

For determination of alcohol in the blood the micromethod of Widmark is indicated as a well known and reliable procedure. As soon as possible following the accident the specimen is drawn from the ear lobe or finger tip and collected in specially prepared glass tubes. The Widmark method has received recognition in an amendment to the criminal procedure statute. In order to save expense the withdrawal of the blood specimen and the clinical examination are con-

sidered a part of the duties of the regular police physician. In order that the greatest possible exactitude and certainty may be obtained in the medical establishment of sobriety or inebriation, a medical examination must in each case be carried out and the observations properly recorded on questionnaire blanks. This procedure is particularly important if the alcoholic content of a suspected person's blood is not great enough to establish an alcoholic influence in the absence of other evidence. An especially valuable feature of the Widmark method is that by it not only the influence of alcohol but a state of sobriety may be determined, this may have a decisive bearing on the release from custody of a suspected person. Since the alcoholic content may be preserved for several weeks in the specially prepared glass tubes, the possibility of a later central examination in the main laboratory of the government hospital is guaranteed the police officials.

separate and distinct department, and urge especially the nomination as chief executive officer of such a department of a qualified physician with a record of achievement in administration.

On January 26, 1937, the President, Dr Winslow, was advised that a resolution requiring emergency action would properly come before the Executive Committee. Under the By-Laws, Chapter V, Section 3 Dr Winslow directed that two questions in this connection be submitted by wire to the members of the Council, as follows

1 To recommend to the Trustees an appropriation of \$2,500 to be sent to the State Medical Societies in the flood area for distribution to physicians in distress

2 To set up a subscription list through county societies for individual donations by members for the same purpose.

A very large majority of the members of the Council approved of such action

The appropriation of \$2,500 for this purpose was considered, as required by the By-laws, by the Board of Trustees in an emergency telephonic meeting. The Board decided that it would be better to withhold approval until information could be secured from the American Medical Association as to the actual existence of distress among the physicians in the flood area. This information was sought immediately and it developed that no actual distress was known—particularly in the two cities which had suffered most heavily. Therefore, it seemed best that no effort be made to open up subscription lists as had been approved in the Referendum Vote of the Council. On February 11, 1937, the Executive Committee decided that further action in the matter be postponed until evidence of need should appear to justify such contributions.

PETER IRVING, M D
Secretary

INSULIN TREATMENT FOR DEMENTIA PRAECOX

A new treatment for dementia praecox is said by eminent American psychiatrists to offer greater promise for the alleviation of the malady than any treatment available so far.

The new treatment, which had been applied during the last three and a half years in European institutions for the insane with results regarded as highly promising, was reported on Jan 12 at a combined meeting of the New York Neurological Society and the Section of Neurology and Psychiatry of the New York Academy of Medicine, held at the Academy Building.

The origin and nature of the treatment, which is based on producing a state of shock by the administration of insulin, was described by the man who first discovered it in 1928—Dr Manfred Sakel, Vienna psychiatrist, who has been invited to this country to instruct American psychiatrists in his method, which, should present promises be realized, will prove one of the great milestones in the treatment of mental ills.

In addition to Dr Sakel, those presenting papers and participating in the discussion included Dr Earl M Bowman, director of the psychiatric division of Bellevue Hospital and Dr Joseph Wortis of the psychiatry departments of Bellevue and New York University Medical College. Dr Bernard Glueck, medical director of Stony Lodge, Ossining, N Y, Professor Adolf Meyer, psychiatrist-in-chief, Johns Hopkins Hos-

pital, Baltimore, Dr John R Ross, superintendent of the Harlem Valley State Hospital, Wingdale, N Y, and Dr W B Cline Jr of the staff of the Wingdale institution, Dr Clarence O Cheney of the Psychiatric Institute, and Dr Smith Ely Jelliffe and Dr D Ewen Cameron.

As Dr Glueck expressed it "Time alone will tell how permanent the alleged cures are."

"My own experience," Dr Sakel said, "now includes over 300 cases, and there were as many more cases treated by others. But I am perfectly well aware of the difficulty there must be in reducing the material to statistics so that the value of this new treatment of schizophrenia (dementia praecox) can be estimated."

"The natural fluctuation which occurs in the course of the disease, the absence of the kind of definite symptoms that we have in physical diseases, and the impossibility of making a certain prognosis in any one case, all make it difficult to estimate results, especially when the case material is small."

"But when in so large a series of cases as I have treated up to now, and with the results confirmed by others, the net result is a percentage of remissions which is at least four times greater than the most optimistic figures for spontaneous remissions, then I think, no matter how cautious we may be, we are entitled to conclude that the treatment is effective."

EXECUTIVE COMMITTEE PROCEEDINGS

At its meetings on January 14 and February 11, 1937 the Executive Committee considered at length a number of subjects which are now before the standing committees. Many matters require still further study, but in some instances the Committee has arrived at final conclusions.

The following Advisory Committee to the Committee on Legislation was appointed

Harry Aranow	New York City
Blinn A. Buell	Binghamton
Henry C. Courten	Richmond Hill
George M. Fisher	Utica
William W. Hall	Watertown
Horace M. Hicks	Amsterdam
H. J. Knickerbocker	Geneva
Morton Ryder	Rye
G. Scott Towne	Saratoga Springs
Earle W. Voorhees	Poughkeepsie

On recommendation of the Committee on Economics, the following opinion was recorded

That it be the expressed opinion of the Medical Society of the State of New York that groups of physicians, practicing as such, should remain within the same framework of restrictions as to their conduct as though the activity were that of an individual physician. In other words, we feel that a group may not obtain publicity, by any means, in lay publications, that it should not solicit or advertise, that it should not claim superior quality or service and it should not practice competitive fees against the individual physicians of the community. If the group conforms to this and relies solely upon the recognition of its service by the people of the community as its sole means of acquisition of patronage it would seem to be a proper and fair activity. On the other hand, if the group by subterfuge courts the patronage of the community by enjoying any form of publicity, it would seem to us that each member physician should be considered personally guilty of misconduct.

Consideration of the matter of medical expense indemnity insurance in the State of New York, which had been the subject of long study by the Committee on Economics, led to the adoption of the following report of a special committee of the Executive Committee

1 We define medical expense indemnity insurance as a form of insurance whereby an individual, by making payments of stated premiums, purchases a definite sum of money in cash, which is thus made available to him for the payment of the individual's physician's charges for professional services. We recom-

mend endorsement of such a form of insurance.

2. We would add that in our opinion the physician's claims for his professional services should be a first lien on the cash indemnity.

3 That the medical expense indemnity insurance plan must be carried out on an actual basis.

4 That philanthropy has no place in an indemnity insurance scheme or plan, to deliver cash benefits to those who pay its premium requirements, so as to have funds to meet physicians' charges for services.

The Executive Committee received from three members the nomination to Honorary Membership in the Medical Society of the State of New York, as indicated in the following letter

December 22, 1936

Executive Committee,
Medical Society of the State of New York,
2 East 103rd Street,
New York, N. Y.

Gentlemen

The undersigned members desire to nominate for Honorary Membership in the Medical Society of the State of New York

Dr. José Arcé, Professor of Surgery, University of Buenos Aires, Buenos Aires, Argentina.

We beg that you present this at the meeting of the House of Delegates in May, 1937, as prescribed by the By-laws, Chapter I, Section 4.

Very truly yours,

FLOYD S. WINSLOW

JOSEPH J. ELLER

CHAS. GORDON HEYD

The nomination will be submitted to the House of Delegates at its next meeting.

At the suggestion of Dr. James Ewing of New York City, the Executive Committee discussed the merits of creation by the House of Delegates of a new Section or Session on Pathology. The Committee had the pleasure of receiving and listening to Dr. M. J. Fein, Secretary, and Drs. Nathan C. Foot and Ward J. MacNeal, members of the New York State Committee on Economics of Pathology. It was decided to recommend to the House of Delegates the establishment of either a Section or a Session on Pathology.

In connection with the possibility of the setting up under the Federal Government of a department devoted to medical and health activities, the Executive Committee adopted the following resolution

That the Medical Society of the State of New York urge that the reorganization of the federal government combine in one department all medical and health activities making this a

COMMITTEE ON SCIENTIFIC WORK

Announcement of Moving Picture Exhibit at the Rochester Meeting

The interest manifested in the continuous showing of medical motion pictures at the annual meeting in New York City last year, was so overwhelming, and the idea so generally copied by other medical meetings thereafter, that the Committee on Scientific Work will repeat this feature at the meeting in Rochester May 24, 25, and 26, on an even more extensive scale.

Films are requested, and may be offered for projection under the following rules and regulations

1 Owing to the large number of excellent films which have been made during the past year, and are now being submitted for exhibition, it may be impossible to give all this material a place on the program. The committee therefore reserves the right to select a program of films from the material submitted on the basis of general medical interest, scientific content, and technical perfection. Films which are not to be used will be returned as soon as they have been reviewed. Films which are accepted will be returned directly after the close of the exhibit. Expert handling, care, storage, and projection of films while in the custody of the committee is promised.

2 All films must be received for consideration on or before March 15. No film received after that date can be accepted. All films must be sent to Dr. John Henderson, 850 Park Avenue, New York City.

3 Sixteen millimeter safety film only, will be accepted for projection. This may be either monochrome or Kodachrome, with

or without sound on film. Exhibitors who desire to lecture as their film is projected may do so through a microphone connected to the regular sound equipment, thus providing a running annotation which greatly increases the interest of the film.

4 No moving picture equipment may be used in the booths provided for scientific exhibits. All film with the exception of that used in the various scientific and general sessions, must be projected in the "theater" provided for that purpose.

5 The most modern type of projection apparatus, operated by a technical expert will be furnished, and must be used for projection. The use of other equipment cannot be permitted.

6 A suitable room has been provided by the Committee on Arrangements, to be known as the Moving Picture Exhibit Theater. Showings will be continuous, each film appearing at scheduled times. This schedule will be strictly adhered to, and will appear in the printed programs, and upon placards outside the theater. Scientific exhibits in booths which have a film as a component unit will display placards stating the times at which that film will be shown.

The Committee expects to offer a program of outstanding merit and educational value, and it is to this end that the cooperation and generosity of the members of the Medical Society of the State of New York is most earnestly solicited.

Kindly address all communications to Dr. John Henderson, 850 Park Avenue, New York City.

VITAMIN D MILKS ACCEPTED

The Council on Foods of the AMA announce in the *Journal* of Jan. 16 the acceptance of various forms of pasteurized evaporated, and dried milk fortified with vitamin D from cod liver oil, ergosterol, and other sources.

In accepting these vitamin D milks, the Council on Foods made the following statements concerning fortification of milk with Vitamin D.

Consequently it seems to the Council to be in the interests of the public as a whole to rec-

ognize and accept the fortification of food with vitamin D.

The Council believes that a moderate amount of vitamin D in addition to that which is normally obtained is a factor of safety in nutrition and health, at least during the period of growth. If the vitamin D addition during childhood and later years is reasonable, e.g., up to four or five hundred units daily, it is believed that possibly some benefit will ensue and certainly no harm.

Of all the common foods available milk is most suitable as a carrier of added vitamin D.

recommending the reorganization of the Federal Government, one of the provisions of which is that all health activities shall be concentrated in one department, probably the new welfare department. It seems that there can be no objection raised either by the public or by the medical profession to having medical activities collected into one department, but that department should be independent and not a subsidiary bureau of another department. Welfare activities at present are at a peak. It is conceivable that as times improve welfare activities on the part of the Federal Government will decrease, but public health activities will continue to increase in extent and importance for years to come. In order that our Congressmen may have our point of view regarding the reorganization, we have written the following letter to each of them, and we suggest that you, bulletin reader, write to your Congressman somewhat along the same line. He will appreciate having your opinion.

The physicians of New York State are very much interested in reports that come from Washington of plans now under consideration for reorganizing the Government. Naturally, we are most interested in what will become of the various health activities that are now conducted by the Public Health Service and several bureaus in other departments. For several years we have been advocating the concentration of health activities in one department under the direction of a medical man, and it now looks as though our wishes are to be realized.

Your knowledge of the great advances that have been made in the control of epidemics and bacterial diseases in general since the reorganization of our State Department of Health twenty years ago, must convince you of the importance to the State of properly administered public health activities. You will recall that Dr. Biggs, the first Commissioner after the reorganization, insisted that public health is purchasable and that within natural limitations any community can determine its own death rate. He also insisted that the only persons who are qualified and capable of knowing what public health measures should be inaugurated, and how they should be administered, are regular graduates of medicine. New York State was one of the first states to insist upon having all of its health officers qualified by the possession of licenses to practice medicine.

The reorganization scheme was quite revolutionary to the people of that time, but New York's splendid health record of today is entirely the product of the close cooperation that has developed between public health officials and practicing physicians. It is not impossible that a similar benefit may be derived by the whole United States if, in the reorganization plan, health activities are given the importance they deserve.

Speaking for the Committee on Legislation of the Medical Society of the State of New York, may I say that we hope you will see

this matter as we do and insist that supervision of the Nation's health activities be concentrated in a single department, and that not made subservient to another."

Special Bulletin

February 15, 1937

As previously announced, on Friday, February 12th, the Legislative Committee held a conference in Albany with the chairmen of the County Society Committees. Thirty-five County Societies were represented. The bills then before the Legislature were carefully studied. A record of the action taken upon each bill follows.

Senate Int. 20, Pr. 20—Howard—employment agencies—No action.

Comment: It was stated that the features which were objectionable to the nurses have been removed.

Senate Int. 21, Pr. 21—Livingston—social security—No action.

Senate Int. 47, Pr. 47—Williamson—allowance of disbursements under Workmen's Compensation Law—No action.

Comment: Has no relation to medical fees.

Senate Int. 55, Pr. 55—Graves—importation of milk and cream—No action.

Comment: It was stated that milk and cream used for drinking purposes, when imported, must come from dairies that are supervised as closely as those located in the State.

Senate Int. 67, Pr. 371—McNaboe—bureau of narcotic control—Disapproved.

Comment: Its enactment would complicate administration of the Federal Narcotic Law which is considered sufficiently adequate.

Senate Int. 210, Pr. 215—Hanley—settlement of tubercular patients in Livingston County—Approved.

Senate Int. 259, Pr. 265—Twomey—reorganization of Mental Hygiene Department—No action.

Senate Int. 274, Pr. 280—McCall—stamp tax on tobacco—Disapproved.

Comment: Disapproved on the ground that it would establish free dental clinics.

Senate Int. 313, Pr. 319—Feld—medical inspection of school children—Disapproved.

Comment: Representatives from Buffalo, Rochester, and New York felt that medical inspection of school children can be done better by the Department of Health than the Department of Education, and saw no reason for a change.

Senate Int. 316, Pr. 322—Feld—licensing clinical laboratory technicians—Disapproved.

Comment: The definition of a technician is too inclusive, would not permit physician to make his own examinations, would not

COMMITTEE ON LEGISLATION

Bulletin No 4

February 4, 1937

The following bills have been introduced since the issuance of our last bulletin

Senate Int. 397—Feld, Assembly Int 715—Milroe, amends the Education Law relative to the practice of physiotherapy by changing educational requirements and exemptions relative thereto, and providing for revocation of license and disciplinary proceedings Referred to the Education Committees

Comment This bill was prepared by the Department of Education in accordance with a recommendation submitted by a committee appointed by the Regents to make an investigation of the practice of physiotherapy as described in the law That committee considered the matter with our Committee and with several groups of physiotherapists One of the provisions of the amendment is deletion of the section providing for licensure of this type of physiotherapist

Senate Int 481—Twomey, amends the Education Law by striking out from provision that article relative to manufacture and sale of proprietary medicine shall not apply to the sale of such medicine except those which are poisonous, etc Referred to the Finance Committee

Comment The proposed amendment would remove jurisdiction over the sale of proprietary medicines The law at present has jurisdiction over the manufacture and sale of proprietary medicines

Senate Int 483—Twomey, amends the Education Law by defining "chemist" to mean person holding B S degree in chemistry or who has been employed as chemist in manufacturing drugs or medicine for at least five years prior to time act takes effect Referred to the Finance Committee

Senate Int. 484—Twomey, amends the Education Law by providing no pharmacy or drug store shall be registered after July 1, 1937 unless owner is a licensed pharmacist or druggist or shall have had four years' practical experience in pharmacy or drug store, except persons, partnerships or corporations holding certificates Referred to the Finance Committee

Senate Int. 487—Dunkel, adds new section to the Education Law prohibiting sale at wholesale of poisonous or deleterious drugs and medicines or habit-forming drugs, except to those registered by board, section not to apply to sales to state or its subdivisions, or to hospitals, physicians, dentists

or veterinarians Referred to the Education Committee

Assembly Int. 513—Austin, adds new title 4, Labor Law, by regulating hours of labor of employees in charitable or private hospitals, providing for eight consecutive hour day, 48 hour week, minimum 24 consecutive hours for rest, excepts administrative officials, medical staff, superintendents, and ambulance drivers Referred to the Labor Committee

Assembly Int 571—Brownell, creates commission of three senators and two other persons to be appointed by temporary president of Senate, three assemblymen and two others to be appointed by speaker, and three by Governor, two of whom shall be of colored race, to study economic, cultural, health and living conditions of urban colored population, to report on March 1, 1938, and appropriating \$50,000 Referred to the Ways and Means Committee

Assembly Int. 573—Bush, amending the Health Law, prohibiting possession, dispensing or sale after July 1, 1937, by a dispensary without approval of Health Department, of any narcotic preparation described in section 428 Referred to the Health Committee

Assembly Int 574—Bush, amends the Public Health Law by requiring births to be registered within 48 hours instead of five days and relative to issuing certified copies of birth and death certificates, also correcting certain errors Referred to the Health Committee

Assembly Int. 575—Bush, amends the Public Health Law by compelling immediate report by physician examining specimen disclosing communicable disease if results obtained are needed for purposes of release from quarantine or observation Referred to the Health Committee

Assembly Int. 702—E F Moran, amends the Education Law, requiring education boards in cities and union free school districts and school district trustees to employ competent dentists to make inspection of pupils, similar to medical inspection as at present. Referred to the Education Committee

Action on Bills

Assembly Int. 1—Whitney—bovine animals Bang's disease, appropriation—3rd reading

You have read in the newspapers recently the report of the committee to the President

recommending the reorganization of the Federal Government, one of the provisions of which is that all health activities shall be concentrated in one department, probably the new welfare department. It seems that there can be no objection raised either by the public or by the medical profession to having medical activities collected into one department, but that department should be independent and not a subsidiary bureau of another department. Welfare activities at present are at a peak. It is conceivable that as times improve welfare activities on the part of the Federal Government will decrease, but public health activities will continue to increase in extent and importance for years to come. In order that our Congressmen may have our point of view regarding the reorganization, we have written the following letter to each of them, and we suggest that you, bulletin reader, write to your Congressman somewhat along the same line. He will appreciate having your opinion.

The physicians of New York State are very much interested in reports that come from Washington of plans now under consideration for reorganizing the Government. Naturally, we are most interested in what will become of the various health activities that are now conducted by the Public Health Service and several bureaus in other departments. For several years we have been advocating the concentration of health activities in one department under the direction of a medical man, and it now looks as though our wishes are to be realized.

Your knowledge of the great advances that have been made in the control of epidemics and bacterial diseases in general since the reorganization of our State Department of Health twenty years ago, must convince you of the importance to the State of properly administered public health activities. You will recall that Dr Biggs, the first Commissioner after the reorganization, insisted that public health is purchasable and that within natural limitations any community can determine its own death rate. He also insisted that the only persons who are qualified and capable of knowing what public health measures should be inaugurated, and how they should be administered, are regular graduates of medicine. New York State was one of the first states to insist upon having all of its health officers qualified by the possession of licenses to practice medicine.

The reorganization scheme was quite revolutionary to the people of that time, but New York's splendid health record of today is entirely the product of the close cooperation that has developed between public health officials and practicing physicians. It is not impossible that a similar benefit may be derived by the whole United States if, in the reorganization plan, health activities are given the importance they deserve.

Speaking for the Committee on Legislation of the Medical Society of the State of New York, may I say that we hope you will see

this matter as we do and insist that supervision of the Nation's health activities be concentrated in a single department, and that not made subservient to another."

Special Bulletin

February 15, 1937

As previously announced, on Friday, February 12th, the Legislative Committee held a conference in Albany with the chairmen of the County Society Committees. Thirty-five County Societies were represented. The bills then before the Legislature were carefully studied. A record of the action taken upon each bill follows.

Senate Int. 20, Pr. 20—Howard—employment agencies—No action.

Comment: It was stated that the features which were objectionable to the nurses have been removed.

Senate Int. 21, Pr. 21—Livingston—social security—No action.

Senate Int. 47, Pr. 47—Williamson—allowance of disbursements under Workmen's Compensation Law—No action.

Comment: Has no relation to medical fees.

Senate Int. 55, Pr. 55—Graves—importation of milk and cream—No action.

Comment: It was stated that milk and cream used for drinking purposes, when imported, must come from dairies that are supervised as closely as those located in the State.

Senate Int. 67, Pr. 371—McNaboe—bureau of narcotic control—Disapproved.

Comment: Its enactment would complicate administration of the Federal Narcotic Law which is considered sufficiently adequate.

Senate Int. 210, Pr. 215—Hanley—settlement of tubercular patients in Livingston County—Approved.

Senate Int. 259, Pr. 265—Twomey—reorganization of Mental Hygiene Department—No action.

Senate Int. 274, Pr. 280—McCall—stamp tax on tobacco—Disapproved.

Comment: Disapproved on the ground that it would establish free dental clinics.

Senate Int. 313, Pr. 319—Feld—medical inspection of school children—Disapproved.

Comment: Representatives from Buffalo, Rochester, and New York felt that medical inspection of school children can be done better by the Department of Health than the Department of Education and saw no reason for a change.

Senate Int. 316, Pr. 322—Feld—licensing clinical laboratory technicians—Disapproved.

Comment: The definition of a technician is too inclusive, would not permit physician to make his own examinations, would not

permit him to train his office nurse to do them, would disrupt present practice of training technician to do one specific piece of work. Technician's ability is one of skill and for perfection depends upon continual practice. It is inconceivable, therefore, that many persons could qualify as skilled technicians in all of the eleven subjects named in the bill. An examining board consisting of technicians alone would not be desirable.

Senate Int 397, Pr 411—Feld—physiotherapy—Approved

Senate Int 487, Pr 510—Dunkel—poisonous drugs—Approved

Senate Int 573, Pr 600—Wojtkowiak—payment of firemen's medical and hospital expenses—Approved in principle
